## **Overview**

Our avar Stata routine constructs the "filling" for a number of flavors of "sandwich" covariance matrix estimators, including HAC, one- and two-way clustering, common cross-panel autocorrelated errors, etc.

We show how avar may be used as a building block to construct VCEs that go beyond the Eicker–Huber–White and one-way cluster-robust VCEs provided by official Stata's \_robust command. The avar routine may also be used to provide multiple-equation VCE estimates in circumstances not handled by official Stata's suest command. Finally, we demonstrate how avar's capabilities may be utilized in a general-purpose GMM–CUE estimator.

## Introduction

avar is a routine for estimating *S*, the asymptotic variance of (1/N)Z'e, where *Z* is an  $N \times L$  matrix of variables, *e* is an  $N \times p$  matrix of residuals, and *N* is the sample size. Typically, *S* would be used to form a sandwich-type estimate of the variance of an estimator, where *S* is the "filling" of the sandwich.

avar can estimate VCEs for single and multiple equations that are robust to various violations of the assumption of *i.i.d.* errors, including heteroskedasticity, autocorrelation, one- and two-way clustering, common cross-panel disturbances, etc. It supports time-series and panel data.

▲□▶▲□▶▲□▶▲□▶ = のへの

For example, in the most basic application, linear regression, *e* is a  $N \times 1$  vector of residuals from an OLS estimation and *Z* is the  $N \times L$  matrix of regressors.

The variance of the OLS estimator,  $Var(\hat{\beta})$ , can be estimated by the "sandwich"  $N \times DSD$ , where the "filling" *S* is the estimate of the asymptotic variance of (1/N)Z'e and the "bread" is  $D = (1/N)(X'X)^{-1}$ .

This estimate of the variance of the OLS estimator is as robust as is *S*. For instance, if *S* is robust to heteroskedasticity,  $Var(\hat{\beta})$  will be robust as well. If *S* is robust to two-way clustering, so will be  $Var(\hat{\beta})$ .

For example, in the most basic application, linear regression, *e* is a  $N \times 1$  vector of residuals from an OLS estimation and *Z* is the  $N \times L$  matrix of regressors.

The variance of the OLS estimator,  $Var(\hat{\beta})$ , can be estimated by the "sandwich"  $N \times DSD$ , where the "filling" *S* is the estimate of the asymptotic variance of (1/N)Z'e and the "bread" is  $D = (1/N)(X'X)^{-1}$ .

In the multiple-equation context, e is a  $N \times p$  matrix of residuals from p different equations. avar will return an estimate of the asymptotic VCE, including the covariances across equations. avar can estimate an S that coincides with the  $Var(\hat{\beta})$  reported by the Stata routines sureg, reg3 and suest.

In its current implementation, avar employs listwise deletion. This means it will only use observations for which there are no missing values in any of the variables in the evarlist. This is the behavior of sureg and reg3, but not that of suest or gsem.

- cluster(*cvarlist*): one- or two-way cluster-robust VCE; may be combined with bw(#) if data are tsset and one of the variables in *cvarlist* is the time variable
- dkraay(#): VCE robust to autocorrelated cross-panel disturbances with bandwidth=#, per Driscoll and Kraay (*REStat*, 1998); equivalent to cluster(*tvar*) + bw(#) where *tvar* is the time variable
- kiefer: VCE robust to within-panel autocorrelation, per Kiefer
   (*J.Econometrics*, 1980): equivalent to kernel(tru) + bw(#) where # is the full length of the panel

- partial(*pvarlist*): partial out variables in *pvarlist* from variables in *evarlist* and *zvarlist*; constant also partialled-out
- onconstant: suppress constant from zvarlist
- demean: center (demean) variables in *evarlist* and *zvarlist* (implies noconstant)
- smata(*mname*): name for avar matrix left in Mata environment if requested

SQ A

- partial(*pvarlist*): partial out variables in *pvarlist* from variables in *evarlist* and *zvarlist*; constant also partialled-out
- noconstant: suppress constant from zvarlist
- demean: center (demean) variables in *evarlist* and *zvarlist* (implies noconstant)
- smata(*mname*): name for avar matrix left in Mata environment if requested

## avar as a building block

Users can employ avar as a building block for their own estimation routines, whether these estimation routines are intended for a wide audience or are for their own use.

As an example of the former, weakiv by Finlay, Magnusson and Schaffer is an estimation routine for weak-instrument-robust inference, an alternative to standard IV/GMM estimation. This command, available from SSC, can provide estimates for all the non-i.i.d. options supported by avar.

SQ A

## avar as a building block

Users can employ avar as a building block for their own estimation routines, whether these estimation routines are intended for a wide audience or are for their own use.

As an example of the former, weakiv by Finlay, Magnusson and Schaffer is an estimation routine for weak-instrument-robust inference, an alternative to standard IV/GMM estimation. This command, available from SSC, can provide estimates for all the non-i.i.d. options supported by avar.

◆□▶ ◆□▶ ▲目▶ ▲目▶ ▲□▶ ▲□

weakivtest by Montiel Olea, Pflueger and Wang is a postestimation routine for testing for the presence of weak instruments following IV or LIML estimation. Their innovation is that weakivtest calculates the Montiel–Pflueger test (*J.Bus.Ec.Stat.*, 2013), which unlike existing tests can be made robust to various non-i.i.d. alternatives. weakivtest (which the authors wrote independently) uses avar to construct the appropriate robust *S*, and is available from SSC.

The rest of the presentation is an example of the latter: a user-written estimation routine that is designed for a specific problem, GMM–CUE, and that uses avar to construct an appropriate robust *S*.

weakivtest by Montiel Olea, Pflueger and Wang is a postestimation routine for testing for the presence of weak instruments following IV or LIML estimation. Their innovation is that weakivtest calculates the Montiel–Pflueger test (*J.Bus.Ec.Stat.*, 2013), which unlike existing tests can be made robust to various non-i.i.d. alternatives. weakivtest (which the authors wrote independently) uses avar to construct the appropriate robust *S*, and is available from SSC.

The rest of the presentation is an example of the latter: a user-written estimation routine that is designed for a specific problem, GMM–CUE, and that uses avar to construct an appropriate robust *S*.

## **Application: user-specified GMM-CUE**

The features of avar are likely to be most useful when it is used as a building block for other estimation routines. As an illustration, we have constructed a routine to implement a general-purpose GMM-CUE (Generalized Method of Moments/Continously Updated Estimator).

This routine, gmmcue.ado, requires that the user provide a Mata function, m\_gbar(), which takes a single argument: a Mata structure. The function must compute the residuals for each observation, analogous to the way in which a function evaluator for Stata's gmm command works, and computes a matrix gbar which contains the sample average values (1/N)Z'e.

gmmcue (yvarlist) [weight][if][in][, initb(numlist) initbmat(string)
xvars(varlist) zvars(varlist) vceopt(string) ]

where the *yvarlist* may contain one or more dependent variables (or be empty, as we will show); the xvarlist may contain regressors; and the zvarlist may contain instruments. The vceopt choices are those available in avar. Initial parameter values may be provided in initb() or as a matrix from a prior consistent estimation.

gmmcue can handle not only standard regression problems, but other optimization problems which may be solved in the GMM framework. In the Stata manual description of gmm, Example 13 shows how an Euler equation may be fit to consumption, following Hansen and Singleton (*Econometrica*, 1982). Using a constant relative risk aversion (CRRA) utility function, the Euler equation is

$$E\left[z_t\left(1-\beta(1+r_{t+1})(c_{t+1}/c_t)^{-\gamma}\right)\right]=0$$

where  $r_t$  is the interest rate (the return on three-month Treasury bills) and  $c_t$  is aggregate consumption expenditures. In this model,  $\beta$  is the discount factor; it is near 1, the agent is patient, willing to forgo current consumption. If it is near zero, the agent prefers to consume more now. The parameter  $\gamma$  characterizes the utility function; if it is zero, the function is linear, whereas as it nears 1, utility is a function of the log of consumption.

UKSUG14

 $\mathcal{O} \mathcal{Q} \mathcal{O}$ 

We first estimate the model with gmm to get reasonable starting values, using as instruments L.r L2.r cgrowth L.cgrowth, where r is the interest rate and cgrowth is one-period consumption growth:

```
. use http://www.stata-press.com/data/r12/cr, clear
. generate cgrowth = c / L.c
(1 missing value generated)
. gen byte one=1
. qui gmm (1 - {b=1}*(1+F.r)*(F.cgrowth)^(-1*{gamma=1})), ///
> inst(L.r L2.r cgrowth L.cgrowth) wmat(hac nw 4) twostep
. estat overid
Test of overidentifying restriction:
Hansen's J chi2(3) = 14.2532 (p = 0.0026)
. mat b_2step=e(b)
```

UKSUG14

We then invoke gmmcue to estimate  $(\beta, \gamma)$ , using a AC estimator with bandwidth=5, corresponding to four lags:

```
. gmmcue, xvars(F.r F.cgrowth) zvars(L.r L2.r cgrowth L.cgrowth one) ///
> vceopt(bw(5) kernel(bartlett)) initb(1 1) nolog
```

GMM-CUE estimates
vceopt(.) = bw(5) kernel(bartlett)

Number of obs = 239

	Coef.	Std. Err.	Z	P> z	[95% Conf.	Interval]
b1 b2	1.010785 1190646	.0128247 1.034646	78.82 -0.12	0.000 0.908	.985649 -2.146934	1.035921 1.908805
Sargan-Hansen Chi-sq( 3 )	J statistic: P-val =	48.259 = 0.0000				

In these estimates, the agent appears to be patient, and linearity of the utility function cannot be rejected.

UKSUG14 31 / 34

## **GMM-CUE vs. iterated GMM**

Although it is still under development, our gmmcue routine adds a significant capability to Stata. GMM-CUE is not the same as the "iterated GMM" implemented by Stata's gmm command, as the latter does not impose the same constraints in defining the optimum. For instance, in the *i.i.d.* case, GMM-CUE reduces to LIML, but iterating the GMM estimator to convergence does not produce the LIML estimates.

《口》《卽》《臣》《臣》 [] 臣

UKSUG14

Steve Bond argues that "However there is no (asymptotic) efficiency gain in using the iterated GMM estimator compared to using the two-step GMM estimator, and no clear evidence that iterated GMM has better small sample properties." (lecture notes, Nuffield College)

In contrast, Newey and Smith (*Econometrica*, 2004) and Anatolyev (*Econometrica*, 2005) claim that although iterated GMM is asymptotically equivalent to GMM-CUE, the latter has a smaller second order asymptotic bias.

## **Conclusions**

In summary, avar can play a useful role in producing a number of VCE estimates based upon differing assumptions of the underlying error processes, in both a single-equation and multiple-equation framework. Scrutiny of the code illustrates the flexibility and usefulness of Mata's structures and pointer data type. The gmmcue routine illustrates how avar may be used in the context of a general-purpose GMM routine, and adds a useful tool to Stata's GMM capabilities.
