#### Abstract

In dynamic regression models the least-squares coe $\pm$ cient estimators are biased in - nite samples, and so are the usual estimators for the disturbance variance and for the variance of the coe $\pm$ cient estimators. By deriving the expectation of the initial terms in an expansion of the usual expression for the asymptotic coe $\pm$ cient variance estimator and by comparing these with an approximation to the true variance we ${ }^{-}$nd an approximation to the bias in variance estimation from which a bias corrected estimator for the variance readily follows. This is also achieved for a bias corrected coe $\pm$ cient estimator and allows to compare analytically the second-order approximation to the mean squared error of the least-squares estimator and its counterpart for the ${ }^{-r s t-o r d e r ~ b i a s ~}$ corrected coe $\pm$ cient estimator. Two rather strong results on e $\pm$ ciency gains through bias correction for AR(1) models follow. Illustrative simulation results on the magnitude of bias in coe $\pm$ cient and variance estimation and on the scope for erective bias correction and e $\pm$ ciency improvement are presented for some relevant particular cases of the ARX (1) class of models.

## 1. Introduction

In a recent paper, K iviet and Phillips (1998a), we (henceforth referred to by K P) have obtained a higher-order approximation to the bias in the least-squares estimator of the

[^0]coe $\pm$ cients of normal stable ARX (1) models. In another recent paper, K P (1998b), we obtained a higher-order approximation to the bias in estimators of the disturbance variance based on the sum of squared least-squares residuals divided by alternative measures for the degrees of freedom. A natural extension to this work is to examine the bias in estimators for the variance of the coe $\pm$ cients. In this paper we have a closer look at the second moment of the least-squares estimator for the full vector of coe $\pm$ cients. In addition, we also examine the variance and mean squared error of a bias corrected estimator. From the results various conclusions can be drawn on the e®ectiveness of bias correction and on appropriate variance estimation of (bias corrected) leastsquares estimators in the ${ }^{-}$rst-order stable dynamic regression model. In this class of models the dependent variable is explained linearly by an arbitrary number of strongly exogenous regressor variables and by the one period lagged dependent variable, and it depends on additive normally distributed (i.i.d.) disturbances.

In the stable model the coe $\pm$ cient of the lagged dependent variable is smaller than one in absolute value (we have analyzed the - nite sample characteristics of the ${ }^{-}$rst two moments of the least-squares coe $\pm$ cient estimators in dynamic models with a unit root in KP 1999). We obtain our approximations to ${ }^{-}$nite sample moments by extending the approach followed by Nagar (1959) in such a way that the approximation errors of the results are of order $\mathrm{T}^{\mathrm{i}}{ }^{1}$ or $\mathrm{T}^{\mathrm{i}}$ or even smaller, where T is the sample size. This requires the development of a Taylor-type expansion and then the analytical evaluation of the expectation of expressions which involve terms consisting of products of up to four quadratic forms in standard normal vectors. The approximation of the moments of statistical estimators in stable autoregressive models by use of asymptotic expansions has been undertaken for about half a century. M ost early work is particularly concerned with the estimator of the serial correlation coe $\pm$ cient in a ${ }^{-}$rst order autoregressive Gaussian process, see B artlett (1946), Hurwicz (1950), K endall (1954), M arriott and Pope (1954) and White (1961). In the latter study, which focuses on the AR (1) model with no (or a known) intercept, an analysis is also given of the bias in the variance estimator of the coe $\pm$ cients, but generally speaking very little work has been done to ${ }^{-}$nd out how well the usual standard deviation estimator estimates the true standard errors in dynamic econometric models.

Our results concern a more general model than the AR(1), because we allow for any number of arbitrary exogenous regressors in the autoregressive model and any form of pre-sample initial condition of the dependent variable of this dynamic system. As in K P (1998a, 1998b), for related work see also KP $(1993,1994)$ and Kiviet et al. (1995), the focus of attention is here the bias of ordinary least-squares (OLS) estimation (i.e. Maximum Likelihood conditional on $\mathrm{y}_{0}$ and X ) of all the regression coe $\pm$ cients in the ${ }^{-}$rst-order normal linear dynamic regression model

$$
\begin{equation*}
y=, y_{i 1}+x^{-}+u ; \tag{1.1}
\end{equation*}
$$

where $y=\left(y_{1} ;::: ; y_{T}\right)^{0}$ is a $T £ 1$ vector of observations on a dependent variable, $y_{i_{1}}$ is the $y$ vector lagged one period, i.e. $y_{i_{1}}=\left(y_{0} ; \cdots ; y_{T_{i 1}}\right)^{0}$, and $X$ is a full
column-rank T $£ \mathrm{k}$ matrix of observations on $\mathrm{k}^{-}$xed or strongly exogenous regressors (such as a constant, a linear trend, step/impulse/ seasonal dummy variables or any other covariates not aßected by feedbacks from the dependent variable). The scalar coe $\pm$ cient, (with $\mathrm{j}, \mathrm{j}<1$ ) and $\mathrm{k} £ 1$ coe $\pm$ cient vector ${ }^{-}$are unknown, and $u$ is a $\mathrm{T} £ 1$ vector of independent Gaussian disturbances with zero mean and constant variance $3 / 4$. Below we shall give further attention to the precise assumptions made on the initial conditions, i.e. concerning yo.

We ${ }^{-}$rst focus on an examination of the - nite sample bias of the usual estimator of the (asymptotic) variance of the OLS estimator (B8) of the full coe $\pm$ cient vector ${ }^{\circledR}=$ (.; $9^{\text {a }}$, and we shall develop a bias corrected variance estimator. We shall also consider a bias corrected estimator $\circledR^{\circledR}$ of ${ }^{\circledR}$ and examine its relative $\mathrm{e} \pm$ ciency analytically and also experimentally in simulations. Rewriting (1.1) as

$$
\begin{equation*}
y=Z ®+u ; \tag{1.2}
\end{equation*}
$$

where $Z=\left[y_{i} 1: X\right]$; the OLS estimator of the $(k+1) £ 1$ vector $®$ is

$$
\begin{equation*}
(B)=\left(Z^{0} Z\right)^{i^{1} Z} q ; \tag{1.3}
\end{equation*}
$$

and, based on regularity conditions and some asymptotic and ${ }^{-}$nite sample arguments, its variance $V($ (B) $)=E\left[{ }^{(8)} ; E(\right.$ (B) $]\left[{ }^{(B)} ; E(\text { (B) }]\right]^{0}$ is usually estimated by

$$
\begin{equation*}
\hat{V}(\mathbb{B})=s^{2}\left(Z^{0} Z\right)^{i^{1}} ; \tag{1.4}
\end{equation*}
$$

where

$$
\begin{equation*}
s^{2}=\frac{\left.(y i z \text { © })^{\prime} q_{y i} Z \text { © }\right)^{2}}{T i k i 1} \tag{1.5}
\end{equation*}
$$

Occasionally the degrees of freedom correction is omitted and $3 / 4$ is estimated by the ML estimator

$$
\begin{equation*}
3 \times 2=\frac{\left(y_{i} Z \mathbb{B}\right) 9 y_{i} Z(\mathbb{B})}{T}: \tag{1.6}
\end{equation*}
$$

The coe $\pm$ cient variance estimator $3 \times 2\left(Z^{O} Z\right)^{i 1}$ disregards any ${ }^{-}$nite sample considerations.

Note that the derivation of moments such as $E(\mathbb{B}) ; \mathrm{V}$ (®) and $\mathrm{E}[\widehat{\mathrm{V}}(\mathbb{B})]$ is nontrivial, because $Z$ is stochastic and depends linearly on $u$; whereas © depends nonlinearly on $Z$; so these are moments of expressions which are all highly nonlinear in $u$. Below in Section 2 we ${ }^{-}$rst rewrite $Z$ in such a way that its dependence on $u$ becomes fully explicit, and next we produce for the various moments of interest expansions consisting of individual terms whose expectations can be obtained analytically upon using some basic results which are collected in A ppendix A. From these we obtain approximations to the MSE (mean squared error) and the true variance of © in the general ARX (1) model, and also to the expectation of estimators of this variance. Even though we do not have a representation for the true variance (but only an asymptotic
approximation), these results can be used to develop a bias correction to the standard asymptotic variance estimator. In Section 3 we examine the ${ }^{-}$rst and second moments of an implementation of a bias corrected estimator, which is unbiased to order $\mathrm{T}^{1}{ }^{1}$ : In Section 4 we specialize the general results and examine their implications for the speci ${ }^{-}$c case of a simple AR (1) model with an unknown intercept. Some remarkably simple analytic results on the scope for e $\pm$ ciency gains are obtained. In Section 5 we verify the numerical magnitude of the bias of alternative variance estimators by M onte Carlo simulation. Finally, in Section 6, we summarize our main conclusions. Proofs of our ${ }^{\text {- }}$ ndings can be found in a series of A ppendices.

## 2. Bias of variance estimators in ARX (1) models

The starting point for our analysis is summarized as follows.
Assumption 2.1: In the ${ }^{-}$rst-order dynamic regression model $y=, y_{i 1}+X^{-}+u$, where the scalar , and the $\mathrm{k} £ 1$ vector ${ }^{-}$are unknown coe $\pm$cients, we have: (i) stability, i.e. $\mathrm{j}, \mathrm{j}<1$; (ii) stationarity, i.e. the matrix $Z=\left[y_{i 1}: X\right]$ is such that $Z^{0} Z=O_{p}(T)$; (iii) the $T £(k+1)$ matrix $Z$ has $\operatorname{rank}(Z)=k+1$ with probability one; (iv) the regressors in $X$ are strongly exogenous; ( $v$ ) the disturbances follow $u$ » $N\left(0 ; 3 / 4 I_{T}\right)$, with $0<3 / 4<1$; (vi) the start-up value has $y_{0} \gg N\left(y_{0} ;{ }^{23 / 4}\right)$, with 0 ! < 1 ; (vii) yo and $u$ are mutually independent.

Note that! = 0 represents the ${ }^{-}$xed start-up case. For any! $>0$ the startup is random, and if $!^{2}=\left(1 ;,^{2}\right)^{1}$ then $\mathrm{f}_{\mathrm{t}} \mathrm{g}$ is a covariance stationary process (but possibly with a non-constant mean). Also note that (ii) excludes a linear trend or any $I(1)$ regressors. However, the presence of such variables will not change our approximation formulas as such, as is shown in K P (1998a), but will only render them more accurate, because it reduces their order of magnitude and also the order of the remainder terms.

In order to distinguish the ${ }^{-}$xed and stochastic elements of the regressor matrix $Z$, we decompose $Z=\bar{Z}+\bar{Z}$, where $\vec{Z}$ is de ${ }^{-}$ned as the mathematical expectation of $Z$ conditional on $X$ and $y_{0}$, i.e.

$$
\begin{equation*}
\mathcal{Z}=E(Z)=\left[E\left(y_{i 1}\right): X\right]=\left[y_{i_{1}} \div X\right] \tag{2.1}
\end{equation*}
$$

and
where $e_{1}=(1 ; 0 ;::: ; 0)^{0}$ is a unit vector of $k+1$ elements. It follows directly from
model (1.1) that
where $X^{0}=\left[x_{1} \vdots \Phi \$ \Phi: x_{T}\right]$, and hence we ${ }^{-}$nd that $\bar{Z}$ is determined by: $X ;{ }_{\psi_{0}}{ }^{-}$and . Also de ${ }^{-}$ning $v=\left(u_{0} ; u_{1} ;::: ; u_{T}\right)^{0}$ such that

$$
\begin{equation*}
v \gg N\left[0 ; 3 /\left.4\right|_{T+1}\right] \text { with } y_{0}=y_{0}+!u_{0} ; \tag{2.4}
\end{equation*}
$$

and de- ning the $T £(T+1)$ matrix $G$ such that
one can easily verify that

$$
\begin{equation*}
y_{\mathrm{i} 1}=G v \text { and } \bar{Z}=G v e_{1}^{0}: \tag{2.6}
\end{equation*}
$$

Note, that in the ${ }^{-}$xed start-up case (! = 0), we simply have $\mathbb{Z}=$ Cue $_{1}^{0}$. However, in the derivations to follow we shall stick to the more general case where the value of ! is arbitrary.

We ${ }^{-}$nd

$$
\begin{align*}
E\left(Z^{0} Z\right) & =E\left(Z^{Z}+G v e_{1}^{0}\right) q\left(Z+G v e_{1}^{0}\right)  \tag{2.7}\\
& =Z^{0} Z+3 / 4 \operatorname{tr}\left(G^{\circ} G\right) e_{1} e_{1}^{0}
\end{align*}
$$

and we shall denote the inverse of $E\left(Z^{\circ} Z\right)$ by $Q$, whereas $q_{1}$ denotes the ${ }^{-}$rst column of $Q$, and $q_{11}$ the ${ }^{-}$rst element of $q_{1}$, hence:

$$
\begin{equation*}
Q=\left[E\left(Z^{0} Z\right)\right]^{i} ; \quad q_{1}=Q e_{1} ; q_{11}=e_{1}^{0} Q e_{1}: \tag{2.8}
\end{equation*}
$$

Using the same notation the following result has been proved in KP (1998a).
Theor em 2.1: Under Assumption 2.1 the bias of the least-squares estimator (1.3) can be approximated to ${ }^{-}$rst order as

In fact, K P (1998a) presents a more accurate and complicated approximation to the bias of © ${ }^{(8)}$ which gives the bias to second order. However, for our present purposes the $\mathrm{O}\left(\mathrm{T}^{i}{ }^{1}\right)$ bias approximation of Theorem 2.1 su $\pm$ ces. In order to obtain such an approximation one has to ${ }^{-}$nd an expansion (in this particular case of the estimation error) in such a form that successive terms are of decreasing order so that the order of the remainder term is known, whereas the individual terms in the expansion have an expectation which can be derived analytically. Irrespective of whether one wants to approximate (the bias in) the ${ }^{-}$rst or the second moment of estimators for the coe $\pm$ cients (or for the disturbance variance), the typical expansion will involve terms in which particular types of expressions occur frequently. For some of these typical expressions Appendix A provides their expectation.

We shall present results now that are relevant in order to obtain further insight into matters of interest regarding (the estimation of) the second moment of the full vector of least-squares coe $\pm$ cient estimators. In Appendix B we derive:

Theor em2.2: Under A ssumption 2.1 we ${ }^{-}$nd for the variance of the estimator (®) the approximation:

```
V(*)}=Ef[(*);E(*)][(*); E (*) ] g =
3/4Q
+3/4
```

```
    +Q #
```

```
    +\mp@subsup{q}{1}{}\mp@subsup{q}{1}{0}\mp@subsup{z}{}{\prime}9C+C9#
```

```
        +Q Z
```

```
    +\mp@subsup{q}{11}{}[2tr(\mp@subsup{G}{}{0}G\mp@subsup{G}{}{0}G); 8tr(G}\mp@subsup{}{}{\circ}GCC); 4tr(\mp@subsup{G}{}{0}C'CG
        +4tr(GG}\mp@subsup{}{}{\circ}C)\operatorname{tr}(\mp@subsup{Q}{}{\prime}\mp@subsup{Z}{}{\circ}CZ)]\mp@subsup{q}{1}{}\mp@subsup{q}{1}{0
```

```
        +6Q Z}\mp@subsup{}{}{\circ}\mp@subsup{C}{}{0}Z\mp@subsup{q}{1}{}\mp@subsup{q}{1}{0}+6\mp@subsup{q}{1}{}\mp@subsup{q}{1}{0}\mp@subsup{Z}{}{0}CZZQ)
    +2q2
+20//4}\mp@subsup{q}{11}{2}[tr(GGC)\mp@subsup{]}{}{2}\mp@subsup{q}{1}{}\mp@subsup{q}{1}{0
+O(Ti }\mp@subsup{}{}{2}\mathrm{ ):
```

Next we shall examine how closely the above rather complex approximation to the actual variance of the coe $\pm$ cient estimator corresponds to the expectation of the usual estimator for this actual variance. In Appendix C we prove:

Theor em 2.3: Under Assumption 2.1 we ${ }^{-}$nd for the expectation of the usual estimator of $\mathrm{V}(\mathbb{B})$ given in (1.4) the approximation

$$
\begin{aligned}
& \mathrm{E}[\hat{\mathrm{~V}}(\mathbb{B})]=\mathrm{E}\left[\mathrm{~s}^{2}\left(\mathrm{Z}^{0} \mathrm{Z}^{\mathrm{i}}\right)^{1}\right]= \\
& 3 / 4 \mathrm{Q} \\
& +3 / 44^{4}\left[\operatorname{tr}\left(Q^{\frac{1}{Z}}{ }^{0} G G{ }^{2}\right) \text { i } \frac{2}{T} \operatorname{tr}\left(C^{\circ} C\right)\right] q_{1} q_{1}^{0}
\end{aligned}
$$

$$
\begin{aligned}
& +23 / 8 q_{11} \operatorname{tr}\left(G^{0} G^{G} G\right) q_{1} q_{1}^{0}+o\left(T^{i 2}\right):
\end{aligned}
$$

Note that the approximation to order $\mathrm{T}^{i 1}$ (the leading term) of both V (B) and $\mathrm{E}[\hat{\mathrm{V}}$ (®) $]$ is simply $3 / 4 \mathrm{Q}+\mathrm{o}\left(\mathrm{T}^{\left.{ }^{1}\right)}\right.$ ): However, the second-order approximations of V ( ${ }^{\circledR}$ ) and $\mathrm{E}[\hat{\mathrm{V}}(\mathbb{B})]$ di ®er a lot with respect to contributions of order $\mathrm{T}^{i}{ }^{2}$. Note that Theorem 2.3 implies that the ${ }^{-}$rst-order approximation to $E\left[372\left(Z^{\circ}\right)^{i}{ }^{1}\right]$; the estimator which omits a degrees of freedom correction, is given by $3 / 4 \mathrm{Q}+0\left(\mathrm{~T}^{{ }^{1}}\right)$ too; so, the degrees of freedom correction does not arect the leading term. Since the second-order approximation to $\left.E[3 \not)^{2}\left(Z^{\circ} Z\right)^{i 1}\right]$ equals the expression given in Theorem 2.3 plus the term $; \frac{\mathrm{k}+13 / 4 \mathrm{Q}}{\mathrm{T}}$ we ${ }^{-}$nd that this di ®ers from both the expressions given in $T$ heorems 2.2 and 2.3. Whether or not these di ®erences have an actual magnitude that is worth bothering about has to be found out by numerical evaluation of these expressions for given values of $X$; $y_{0}$; $\circledR^{\circledR}$ and $3 / 4$ at relevant sample sizes $T$; and by comparing these approximative expressions with estimates of the true variance. The latter can be obtained from Monte Carlo experiments.

If these di ßerences can be substantial it would seem interesting to develop a corrected estimator of $\mathrm{V}($ ( $)$; say $\mathrm{V}\left({ }^{(8)}\right)$; which adds particular terms to the standard estimator $\hat{V}$ ( © ) ; such that $E[V(\mathbb{B})]$ is equivalent to second order to V ( © ): We return to the issue of bias reduction of variance (and coe $\pm$ cient) estimators later.

A more focussed comparison of the above analytical results on variance matrices is possible if we limit ourselves to the simpler scalar results for the single lagged dependent variable coe $\pm$ cient , . From Theorem 2.1 one easily obtains:

Corollary 2.1: Under Assumption 2.1 the bias of the least-squares estimator $\hat{\text {, can }}$ be approximated as:

$$
E\left(\hat{,}_{\mathrm{i}},\right)=\mathrm{i}^{3 / 2}\left[q_{11} \operatorname{tr}\left(Q^{-1} C \mathcal{Z}\right)+q_{1}^{0} \mathcal{Z}^{0} C \mathcal{Z} q_{1}+23 / 2 q_{11}^{2} \operatorname{tr}\left(G G^{0} C\right)\right]+o\left(T^{i 1}\right):
$$

From Theorem 2.2 we obtain after pre- and postmultiplication by $\mathrm{e}_{1}$ :
Corollary 2.2: Under Assumption 2.1 we ${ }^{-}$nd for the variance of the estimator $\hat{\text {, }}$ the approximation:

$$
\begin{aligned}
& V(\hat{\jmath})=E[\hat{\jmath} \mathrm{i} \mathrm{E}(\hat{\jmath})]^{2}= \\
& 3 / 4 q_{11} \\
& +3 / 44^{f} 5\left(q_{1}^{0-2}{ }^{0} C Z^{-} q_{1}\right)^{2}
\end{aligned}
$$

$$
\begin{aligned}
& \left.+3 / 46 \mathrm{f} 36 q_{11}^{2} \operatorname{tr}\left(\mathrm{GG}^{\circ} C\right)\left(q_{1}^{0} \mathcal{Z}^{\circ} C Z^{2} q_{1}\right)\right] \\
& +q_{11}^{3}\left[2 \operatorname{tr}\left(G^{\circ} G G^{\circ} G\right) ; 8 \operatorname{tr}\left(G^{\circ} G C C\right) \text { i } 4 \operatorname{tr}\left(G^{\circ} C^{\circ} C G\right)\right. \\
& \left.+4 \operatorname{tr}\left(\mathrm{GG}^{\circ} \mathrm{C}\right) \operatorname{tr}\left(\mathrm{QZ}^{\circ} \mathrm{C} \mathcal{Z}\right)\right] g \\
& +203 / 49_{11}^{4}\left[\operatorname{tr}\left(\mathrm{GG}^{0} \mathrm{C}\right)\right]^{2} \\
& +o\left(T^{i 2}\right):
\end{aligned}
$$

From Theorem 2.3 we obtain:
Corollary 2.3: Under Assumption 2.1 we ${ }^{-}$nd for the expectation of the usual estimator of the variance of the estimator $\hat{\text {, the approximation: }}$

$$
\begin{aligned}
& E[\hat{V}(\hat{\jmath},)]=E\left[s^{2} e_{1}^{0}\left(Z^{0} Z\right)^{i} e_{1}\right]= \\
& 3 / 4 q_{11}
\end{aligned}
$$

$$
\begin{aligned}
& +23 / 4 q_{11}^{3} \operatorname{tr}\left(G^{9} G^{9} G\right)+o\left(T^{i}\right):
\end{aligned}
$$

A gain we note that the two approximations given in Corollaries 2.2 and 2.3 di Rer substantially with respect to their order $\mathrm{T}^{\mathrm{i}}$ terms, which may be an indication that there is some scope for developing a second-order unbiased estimator $\mathrm{V}(\hat{\jmath})$ for $\mathrm{V}(\hat{\jmath}$ ).

## 3. The e $\pm$ ciency of bias corrected coe $\pm$ cient estimators

The approach layed out in the foregoing section consists of three stages: (i) assess the second moment of a coe $\pm$ cient estimator to second order and next (ii) obtain to
second order the expectation of a variance estimator of that coe $\pm$ cient estimator, in order (iii) to exploit these results to correct the variance estimator such that it will become unbiased to second order. This can also be applied to a bias corrected leastsquares estimator in which the result of $T$ heorem 2.1 has been exploited such that the corrected estimator is unbiased to order $\mathrm{T}^{\mathrm{i}}$ : For the expression
it is obvious that this has expectation $\circledR+0\left(T^{i}\right)^{2}$; but it is not an operational estimator, because $3 / 4$; C; G and Q are, or depend on, unknown parameters. However, consider the operational corrected least-squares (COLS) estimator

$$
\begin{equation*}
®={ }^{\circledR}+s^{2} \operatorname{tr}\left(P \hat{Z}^{0} \hat{C} \hat{Z}\right) p_{1}+s^{2} P \hat{Z}^{0} \hat{C} \hat{Z} p_{1}+2 s^{4} p_{11} \operatorname{tr}\left(\hat{C}^{0} C^{0}\right) p_{1} ; \tag{3.1}
\end{equation*}
$$

where © ${ }^{*}$ and $s^{2}$ are the usual least-squares estimators, $P=(Z Z)^{1}{ }^{1}$; which has ${ }^{-}$rst column $p_{1}$ with ${ }^{-}$rst element $p_{11} ; \hat{Z}=\left[\hat{F} y_{0}+\hat{C X} \hat{: X}\right]$ and $\hat{C}$ equals $C$ (also $\hat{F}$ equals $F$ ) with the unknown, replaced by ${ }^{\wedge}$. In Appendix $D$ we prove:

Theor em 3.1: Under A ssumption 2.1 the COLS estimator ${ }^{\circledR}$ given in (3.1) is unbiased to order $\mathrm{T}^{\text {i }}$; i.e.

$$
E(®)=\circledR+O\left(T^{i 1}\right):
$$

For this bias corrected estimator we obtain in Appendix E:
Theor em 3.2: Under Assumption 2.1 we ${ }^{-}$nd for the variance of the bias corrected estimator ${ }^{\circledR}$ given in (3.1) the approximation:

$$
\begin{aligned}
& V(®)=E f\left[{ }^{\circledR} ; \quad E(®)\right]\left[{ }^{\circledR} ; \quad E(®)\right]^{1} g= \\
& 3 / 4 \mathrm{Q}
\end{aligned}
$$

$$
\begin{aligned}
& \left.+q_{11} \operatorname{tr}\left(G G^{\circ} C\right)\left[Q^{-1} C Z^{-} q_{1} q_{1}^{0}+q_{1} q_{1}^{0} Z^{\circ} C^{\circ} Z^{2} Q\right)\right] g \\
& +43 / 8 q_{11}^{2}\left[\operatorname{tr}\left(G^{0} C\right)\right]^{2} q_{1} q_{1}^{0} \\
& +o\left(T^{i}\right)^{2} \text { : }
\end{aligned}
$$

It is noteworthy that the expression for the second order contribution to the variance of the corrected estimator is in fact much simpler than for the uncorrected least-squares estimator.

Theor em 3.3: Under Assumption 2.1 the estimator V ( $®$ ) of the variance of the bias corrected estimator $\circledR$ given in (3.1) has $E[V(®) ; V(®)]=o\left(T^{i^{2}}\right)$ if we de ${ }^{-}$ne:

```
\(V\left({ }^{\circledR}\right) \quad \hat{V}\left({ }^{(8)}\right.\)
    \(+s^{4} f\left[\operatorname{tr}\left(P \mathcal{Z}^{0} \hat{C} Z \hat{P} P \mathcal{Z}^{0} \hat{C} \hat{Z}\right)+\frac{2}{T} \operatorname{tr}\left(\hat{C}^{0} \hat{C}\right)\right] p_{1} p_{1}^{0}\)
```

```
\(\left.+2 s^{6} \operatorname{tr}\left(\hat{C}^{0} C^{\hat{C}}\right) f 2\left(p_{1}^{0} \mathcal{Z}^{0} C^{2} \hat{Z} p_{1}\right) p_{1} p_{1}^{0}+p_{11}\left[P \mathcal{Z}^{0} \hat{C} \hat{Z} p_{1} p_{1}^{0}+p_{1} p_{1}^{0} \mathcal{Z}^{0} C^{0} \mathcal{Z}^{2} P\right)\right] g\)
\(+4 s^{8} p_{11}^{2}\left[\operatorname{tr}\left(\text { C }^{0} C^{\wedge}\right)\right]^{2} p_{1} p_{1}^{0}\) :
```

Specializing the above results to the variance of the ${ }^{-}$rst element of $\circledR$ yields:
Corollary 3.2: Under Assumption 2.1 we ${ }^{-}$nd

$$
\begin{aligned}
& V(,)=E[, i E(,)]^{2} \\
& =3 / 4 q_{11}+
\end{aligned}
$$

$$
\begin{aligned}
& +43 / 462 q_{11}^{2} \operatorname{tr}\left(G G^{\circ} C\right)\left(q_{1}^{0} \mathcal{Z}^{\circ} C Z q_{1}\right)+q_{11}^{3} \operatorname{tr}\left(G^{\circ} G^{\circ} G\right) g \\
& +43 / 8 q_{11}^{4}\left[\operatorname{tr}\left(G^{Q} C\right)\right]^{2}+o\left(T^{i}\right):
\end{aligned}
$$

and
Corollary 3.3: Under Assumption $2.1 \mathrm{~V}($,$) is unbiased to second order for \mathrm{V}(\hat{\jmath}$ ) when de- ning:

$$
\begin{aligned}
& \mathrm{V}(,)^{\prime} \hat{\mathrm{V}}(\hat{\jmath})+
\end{aligned}
$$

$$
\begin{aligned}
& +p_{11}^{2}\left[\frac{2}{\mathrm{~T}} \operatorname{tr}\left(\mathrm{C}^{\circ} \mathrm{C}\right)+\operatorname{tr}\left(\mathrm{P} \hat{Z}^{\circ} \mathrm{C}^{\wedge} \mathrm{C}^{\circ} \mathrm{Z}\right)+\operatorname{tr}\left(\mathrm{P} \hat{Z}^{\circ} \mathrm{C}^{\wedge} \hat{Z}^{\circ} \mathrm{P} \hat{Z}^{\circ} \mathrm{C} \hat{Z}\right)\right] g \\
& +8 s^{6} p_{11}^{2} \operatorname{tr}\left(\hat{C C}^{\circ}{ }^{\circ}\right)\left(p_{1}^{0} \mathcal{Z}^{\circ}{ }^{\circ} \hat{Z} p_{1}\right) \\
& +4 s^{8} p_{11}^{4}\left[\operatorname{tr}\left(\hat{C C}^{-}{ }^{0} \hat{C}\right)\right]^{2}:
\end{aligned}
$$

In deriving Theorem 3.2 and its Corollary 3.2 we have also obtained an approximation for the M SE of the corrected estimator, because these are equivalent up to the
order of the approximation. Comparison of these with the M SE of the uncorrected estimator, which is of course di Rerent from its variance in the $O\left(\mathrm{~T}^{i}{ }^{2}\right)$ terms due to the $O\left(T^{i}\right)$ coe $\pm$ cient bias, yields information on any $e \pm$ ciency gains or losses by coe $\pm$ cient bias correction.

## 4. Results for the AR(1) model with intercept

Here we focus on the variance of the OLS and COLS estimators for the lagged dependent variable coe $\pm$ cient, in the model of A ssumption 2.1 with an intercept as the only exogenous regressor. Hence, we have here:

$$
\begin{equation*}
y_{t}=, y_{t_{\mathrm{i}} 1}+^{-}+u_{\mathrm{t}}: \tag{4.1}
\end{equation*}
$$

For this model Corollary 2.1 reduces to the well-known K endall (1954) approximation restated here as:

Coroll ary 4.1: Under Assumption 2.1 the bias of the least-squares estimator , for the special case of model (4.1) can be approximated as:

$$
\mathrm{E}(\hat{,} \mathrm{i},)=\mathrm{i} \frac{1}{\mathrm{~T}}(1+3,)+\mathrm{o}\left(\mathrm{~T}^{\mathrm{i} 1}\right):
$$

Hence, this approximation proves to be valid irrespective of the nature of the start-up value $\mathrm{y}_{0}$ : $\mathrm{De}^{-}$ning for model (4.1) the standardized start-up value
we - nd the following approximative expression for the true variance, see A ppendix G :
Corollary 4.2: Under Assumption 2.1 the variance of the least-squares estimator ${ }^{\wedge}$ for the special case of model (4.1) can be approximated as:

$$
\begin{aligned}
V(\hat{\jmath}) & =E[\hat{\jmath} \mathrm{i} E(\hat{\jmath})]^{2} \\
& =\frac{1 \mathrm{i},{ }_{2}^{2}}{\mathrm{~T}} \mathrm{i} \frac{1 \mathrm{i} 4, \mathrm{i} 14,^{2}}{\mathrm{~T}^{2}} \mathrm{i} \frac{1 \mathrm{i},^{2}}{\mathrm{~T}^{2}} \forall_{0}^{\mathrm{a} 2}+!^{\prime}+\mathrm{o}\left(\mathrm{~T}^{\mathrm{i}^{2}}\right):
\end{aligned}
$$

Here the leading term $\frac{1_{\mathrm{i}^{2}}{ }^{2}}{\mathrm{~T}}$ is simply the asymptotic variance of $\hat{,}$ : N otice that in the mean-stationary case, where $\psi_{0}=\frac{-}{1_{i}}$; the approximation does not involve $3 / 4$ nor ${ }^{-}$: Also note that the variance decreases with the variance of the initial value $\mathrm{y}_{0}$ :

For the expectation of the standard variance estimator we ${ }^{-}$nd:
Corollary 4.3: Under Assumption 2.1 the expectation of the estimator for the variance of the least-squares estimator , for the special case of model (4.1) can be approximated as:

$$
\begin{aligned}
\mathrm{E}[\hat{\mathrm{~V}}(\hat{\jmath})] & =\mathrm{E}\left[\mathrm{~s}^{2} \mathrm{e}_{1}^{0}(Z \mathrm{Z})^{\mathrm{i}} \mathrm{e}_{1}\right] \\
& =\frac{1 \mathrm{i},,^{2}}{\mathrm{~T}}+\frac{2+2,+5,{ }^{2}}{\mathrm{~T}^{2}} \mathrm{i} \frac{1 \mathrm{i},^{2^{3}}}{\mathrm{~T}^{2}} \forall_{0}^{\mathrm{a} 2}+!^{\prime}+\mathrm{o}\left(\mathrm{~T}^{\mathrm{i}^{2}}\right):
\end{aligned}
$$

It is obvious that this estimator is unbiased to order $\mathrm{T}^{\mathrm{i}}{ }^{1}$; but biased to order $\mathrm{T}^{\mathrm{i}}{ }^{2}$; since one of its second order terms di ®ers from the corresponding one of Corollary 4.2. So, even though we do not know $V\left(\hat{\jmath}\right.$ ) precisely, we ${ }^{-}$nd from its approximation that the standard estimator is biased, viz.

$$
\begin{equation*}
E[\hat{V}(\hat{\jmath}) \mathrm{o} V(\hat{\jmath})]=\frac{3 ; 2, \mathrm{i}^{2},^{2}}{T^{2}}+o\left(T^{i}{ }^{2}\right): \tag{4.3}
\end{equation*}
$$

If we can modify $\hat{V}\left(\hat{\jmath}\right.$ ) to have the same mean to order $\mathrm{T}^{i}{ }^{2}$ as $\mathrm{V}(\hat{\jmath}$ ), then an approximately unbiased estimator of $\mathrm{V}\left(\hat{\jmath}\right.$ ) will result. Thus, for the case $Z=\left[y_{i_{1}}\right.$ : Il where $\boldsymbol{I}=(1 ;::: 1)^{\text {a }}$, the statistic

$$
s^{2} e_{1}^{0}\left(Z^{0} Z\right)^{i} e_{1} i \frac{3 i 2, i^{2},^{2}}{T^{2}}
$$

is unbiased to $\mathrm{O}\left(\mathrm{T}^{\mathrm{i}}{ }^{2}\right)$ for $\mathrm{V}\left({ }_{\Omega}\right)$ but in practice this estimator is not operational since it depends on, : However, since $E(\hat{,} \mathrm{i})=,O\left(\mathrm{~T}^{\mathrm{i}}{ }^{1}\right)$ we ${ }^{-}$nd:

Theor em4.1: Under Assumption 2.1 the corrected estimator for the variance of the least-squares estimator ${ }^{\wedge}$, for the special case of model (4.1) given by

$$
\mathrm{V}(\hat{\jmath}) \cdot \hat{\mathrm{V}}(\hat{\jmath}) \mathrm{i} \frac{3 \mathrm{i} 2_{,}^{\wedge} \mathrm{i} 9^{\wedge}{ }^{2}}{\mathrm{~T}^{2}}
$$

is unbiased to order $\mathrm{T}^{\mathrm{i}}$; i.e. $\mathrm{E}\left[\mathrm{V}(\hat{\jmath}) \mathrm{i} \mathrm{V}(\hat{\jmath}, \mathrm{O})=\mathrm{o}\left(\mathrm{T}^{\mathrm{i}^{2}}\right)\right.$ :
For the simple model (4.1) our implementation of COLS leads to

$$
\begin{equation*}
, \hat{\jmath}+\frac{1}{T}(1+3 \hat{\jmath})=\frac{T+3}{T} \hat{\jmath}+\frac{1}{T}: \tag{4.4}
\end{equation*}
$$

Exploiting now the analytic results of Section 3 on the COLS estimator for the special case of the $A R(1)$ model with intercept we obtain:

Theor em 4.2: Under Assumption 2.1 the COLS estimator, in the simple model (4.1) has

$$
V(,)=V(\hat{\jmath})+\frac{6 i \sigma_{,}^{2}}{T^{2}}+o\left(T^{i^{2}}\right)
$$

and

$$
\operatorname{MSE}(,)=\operatorname{MSE}(\hat{\jmath})+\frac{5 \mathrm{i} 6, \mathrm{i} 15_{\jmath}^{2}}{\mathrm{~T}^{2}}+\mathrm{o}\left(\mathrm{~T}^{\mathrm{i}}\right) ;
$$

so that, omitting terms of order o( $\mathrm{T}^{\mathrm{i}^{2}}$; we ${ }^{-}$nd

$$
\operatorname{MSE}(,)<\operatorname{MSE}(\hat{\jmath}) \quad \text { for } \mathrm{i} 1<,<\mathrm{i} 0: 811 \text { and for } 0: 411<,<1 \text { : }
$$

The - rst result of this theorem shows that, to the order of the approximation, bias correction will invariably lead to an increase in variance. However, the M SE result indicates that, in the AR(1) model with intercept, bias correction is not bene- cial as far as $\mathrm{e} \pm$ ciency is concerned when $\mathbf{i} 0: 811<,<0: 411$ : In a similar way, it can be derived that in the $A R(1)$ model with no intercept bias correction yields no MSE reduction when $\mathrm{j}, \mathrm{j}<0: 707$ : We conjecture that the greater the number of smooth regressors that are included in an ARX (1) model, the more scope there is to improve e $\pm$ ciency through bias correction.

W hen bias correction has been employed an adequate estimator for the resulting variance is still provided by $\widehat{\mathrm{V}}(\hat{\jmath}$ ), but an operational estimator which is even unbiased to order $\mathrm{T}^{i}{ }^{2}$; is then given by:

$$
\begin{equation*}
V(,)^{\prime} \hat{V}(\hat{\jmath})+\frac{3+2,+3,^{2}}{T^{2}}: \tag{4.5}
\end{equation*}
$$

Bias correction of $A R(1)$ models has been entertained in the literature in many studies, see Copas (1966), Orcutt and W inokur (1969), Rudebusch (1992) and M acK innon and Smith (1998). All these studies based their bias correction on the K endall (1954) approximation to the bias given in Corollary 4.1, although, instead of using (4.4), in all the studies just referred to a bias corrected estimator ${ }_{5}$ has been used which is obtained by solving

$$
\hat{,}={ }_{5} \mathrm{i} \frac{1}{\mathrm{~T}}\left(1+3_{5}\right) ;
$$

yielding

$$
\begin{equation*}
=\frac{T}{T_{i} 3^{\prime}}+\frac{1}{T_{i} 3}: \tag{4.6}
\end{equation*}
$$

For the bias of this corrected estimator we ${ }^{-}$nd

$$
\begin{aligned}
\mathrm{E}(, \mathrm{i},) & =\frac{\mathrm{T}}{\mathrm{~T} \mathbf{i} 3} \mathrm{E}(\hat{\jmath}) \mathrm{i},+\frac{1}{\mathrm{~T} \mathbf{i} 3} \\
& =\mathrm{E}(\hat{\jmath} \mathbf{i},)+\frac{3}{\mathrm{~T} \mathbf{i} 3} \mathrm{E}(\hat{\jmath})+\frac{1}{\mathrm{~T} \mathbf{i} 3} \\
& =\mathbf{i} \frac{1}{\mathrm{~T}}(1+3,)+\frac{3}{\mathrm{~T}_{\mathrm{i} 3},}+\frac{1}{\mathrm{~T} \mathbf{i} 3}+\mathrm{O}\left(\mathrm{~T}^{\mathrm{i}}{ }^{2}\right)
\end{aligned}
$$

$$
\begin{aligned}
& =\frac{3}{T i_{3} 3} i \frac{3}{T}+\frac{1}{T_{i} 3} i \frac{1}{T}+O\left(T^{i^{2}}\right) \\
& =, \frac{9}{T(T i 3)}+\frac{3}{T(T i 3)}+O\left(T^{i^{2}}\right) \\
& =O\left(T^{i}\right)
\end{aligned}
$$

hence, both bias corrected estimators remove the $O\left(T^{i}{ }^{1}\right)$ bias. In fact, however, ${ }_{5}$ is a hybrid bias correction estimator, because the correction also involves a non-random term of order $O\left(T^{i}{ }^{2}\right)$; since $\frac{1}{T_{i}{ }^{3}}=\frac{1}{T^{\prime}}+\frac{3}{T^{2}}+o\left(T^{i}{ }^{2}\right)$ : We also ${ }^{-}$nd:

Theor em 4.3: In the simple model (4.1) the corrected estimators, and, are both unbiased to order $\mathrm{O}\left(\mathrm{T}^{i}{ }^{1}\right)$; but, omitting terms of order $\mathrm{o}\left(\mathrm{T}^{\mathrm{i}}\right.$ ) ; , is uniformly (for any $\mathrm{j}, \mathrm{j}<1$ ) more $\mathrm{e} \pm$ cient than ${ }_{5}$; because

$$
V(,)={\frac{\mu}{T} 3^{\boldsymbol{q}_{2}}}_{T} V(\hat{\jmath}) \quad \text { and } \quad V\left({ }_{5}\right)={\frac{\mu}{T_{i} 3}}^{\boldsymbol{q}_{2}} V(\hat{\jmath}):
$$

The superiority of our implementation of bias correction follows from $\frac{\mathrm{T}+3}{\mathrm{~T}} \mathrm{i} \frac{\mathrm{T}}{\mathrm{Ti}^{3}}=$ $\mathrm{i} \frac{9}{\mathrm{~T}\left(\mathrm{~T}_{\mathrm{i}} 3\right)}<0$ :

## 5. Numerical results

We shall examine the estimators $\hat{\text {, and , , their e } \pm \text { ciency, the qualities of their respec- }}$ tive (bias corrected) variance estimators and the accuracy of the various asymptotic approximations for model (4.1) and also for the AR (1) model with intercept and linear trend. For that purpose we perform various numerical evaluations and execute some series of Monte Carlo experiments. In what follows we write $\mathrm{V}[\hat{\jmath}]$ for what in fact is the M onte Carlo estimate of $\mathrm{V}\left({ }_{\mathrm{\jmath}}{ }_{\mathrm{\rho}}\right)$. Because we generate many replications the Monte Carlo estimates will be very close to the actual population moments. In the model with intercept only, we write $A \mathrm{~V}_{1}[\hat{\jmath}]$ for the (leading term) asymptotic variance of $\hat{,}$; which is $\left(1 \mathrm{i},{ }^{2}\right)=\mathrm{T}$, and $\mathrm{AV}_{2}[\hat{\jmath}]$ for the second-order asymptotic approximation to $\mathrm{V}(\hat{\jmath})$; which is given by Corollary 4.2. For the mean over the M onte Carlo replications of $\widehat{\mathrm{V}}(\hat{\jmath})$ we simply write $\mathrm{E}[\hat{\mathrm{V}}[\hat{\jmath}]]$; and similarly for $\mathrm{V}[\hat{}, \mathrm{]}]$ of Theorem 4.1 and for $\mathrm{V}[$, ] of Corollary 3.3. In the tables we present results for various values of $\mathrm{j}, \mathrm{j}<1$ and T ; focussing on positive values of, and 10 T 50 and the case ${ }^{-}=0$; $\psi_{0}={ }^{-}=(1 ;)=,0 ;!=0 ; 3 / 4=1$; i.e. the model with a ${ }^{-}$xed start-up and meanstationarity (note from the asymptotic approximations that these values often seem to mitigate the magnitude of the second order terms). All results presented in the tables are invariant with respect to ${ }^{-}$; and most are with respect to $3 / 4$ Often the results are given as ratios. Then values of unity in the tables may indicate unbiasedness and values smaller (greater) than one negative (positive) bias. In order to compare the erect
of bias correction on e $\pm$ ciency we also present the ratio of $\operatorname{MSE}$ [, ] and M SE [ $\hat{,}$ ]; here values smaller than one indicate an $e \pm$ ciency gain due to bias correction.

We focus on the $\operatorname{AR}(1)$ model with intercept ${ }^{-}$rst. Table 5.1 contains results for $\mathrm{T}=10$ : We see from the second column that at such a small sample size the leastsquares estimator is badly and negatively biased (often -50\%), especially for larger values of , : The next column indicates that a ${ }^{-}$rst-order correction of this estimator reduces the bias by about 60\%. Only for small values of, is the asymptotic variance of the least-squares estimator found to be a reasonable indicator of the actual variance. Especially for, values close to one, the asymptotic variance is much too

Table 5.3:

small. A second-order asymptotic approximation to the variance proves to be more accurate. W here the ${ }^{-}$rst-order approximation is much too small, the second-order approximation overshoots, and does so quite seriously for large values of , : T he standard estimator $\hat{V}(\hat{\jmath})$ of the variance of $\hat{\jmath}$, however, is relatively good, although it can have a bias of $\S 30 \%$ or beyond. Also the corrected variance estimator $\vee($,$) shows some$ remaining bias, but generally this bias is mitigated and always the corrected estimator produces a conservative estimator of the actual variance (it never has a negative bias). Hence, we ${ }^{-}$nd that our analytical higher-order asymptotic results on second moments can be used successfully already at a sample size as small as $T=10$; which seems quite remarkable. A ssessing the variance of the bias corrected coe $\pm$ cient estimator reasonably accurately is shown to be possible, according to the - $n d i n g s$ in the last but one column. The - nal column shows the magnitude in $\mathrm{e} \pm$ ciency loss (or gain) due to coe $\pm$ cient bias correction. From the results we see that at this sample size the critical point is actually not , = 0:411; as our earlier analysis suggested, but slightly larger. A pparently e®ects of third-order are sizeable at such a small sample size.

In Table 5.2 we present similar results for $T=20$ : The coe $\pm$ cient bias is smaller now, but still substantial (often $-25 \%$ ). C orrecting for bias is more successful, because it yields a reduction to 20 or $30 \%$ of the original bias. The accuracy of the asymptotic variance is still appalling, but the second-order approximation seems acceptable now as long as , is not too close to unity. The standard variance estimator may show a bias of some $20 \%$, but the corrected estimator is really quite an accurate one. From the - nal column we see that, upon comparing with Table 5.1, the increased sample size o Rers in fact more scope for relative e $\pm$ ciency gains through coe $\pm$ cient bias correction (all ${ }^{-}$gures in the ${ }^{-}$nal column are smaller). The e $\pm$ciency of the corrected estimator can be estimated very precisely, as is shown by the last but one column, and the value for, where correction starts to pay $0 ®$ is just above $0: 4$ now, as was to be expected
from the result in Theorem 4.2.
Increasing the sample size further to $\mathrm{T}=50$ yields results presented in Table 5.3 which show more or less the same pattern, apart from the following. We ${ }^{-}$nd that the potential e $\pm$ ciency gains from bias correction are much more substantial now than the possible losses that occur in cases where , is non-negative but small. Especially for large values of , ; say, $=0: 9$ where the bias is only about $-10 \%, \mathrm{e} \pm$ ciency gains of about $40 \%$ can be achieved (and for , > 0 e $\pm$ ciency losses never exceed $10 \%$ ), whereas a very accurate estimator of this improved e $\pm$ ciency is available, as can be seen from the last but one column. Note that a MSE reduction of $40 \%$ implies a reduction of some $25 \%$ in terms of root mean squared errors (or standard errors). This seems quite attractive against the risk of a possible increase by only $5 \%$. Hence, these three tables show that it is not necessarily the case that bias correction is called for only when biases are huge. A better eßect on e $\pm$ ciency is obtained when we correct for bias in cases where the bias is moderate, so that the bias approximation is reasonably accurate and therefore more e®ective.

In Table 5.4 we present results for the alternative bias corrected estimator ${ }_{5}$ for all three sample sizes examined. Surprisingly we ${ }^{-}$nd that the less e $\pm$cient estimator , is much less biased than, : It seems to be an artifact that the e®ect that the correction in ${ }_{5}$ has on the order $\mathrm{O}\left(\mathrm{T}^{i}{ }^{2}\right)$ term of the bias happens to be such that it mitigates the magnitude of this term. It is easy to show that the estimator

$$
\begin{equation*}
V\left({ }^{2}\right)^{\prime} \hat{V}(\hat{\jmath})+\frac{3+2^{2}+3^{2}}{T^{2}} \tag{5.1}
\end{equation*}
$$

is unbiased to order $\mathrm{O}\left(\mathrm{T}^{\mathrm{i}}{ }^{2}\right)$ for $\mathrm{V}\left({ }_{5}\right)$ : From the simulations we ${ }^{-}$nd, however, that this estimator is less accurate than $\mathrm{V}(\mathrm{s})$ is for $\mathrm{V}($,$) ; especially so for the smaller sample$
sizes. For $\mathrm{T}=10$ the better e $\pm$ ciency of, is apparent, but the smaller ${ }^{-}$nite sample bias of ${ }_{5}$ leads to satisfactory M SE results close to the unit circle.

Now we present a few results for the AR (1) model with intercept and trend. We just examine the case where ${ }^{-}=0$ (both intercept and trend are redundant), $\psi_{0}=0$ and ! = 0 ( ${ }^{-}$xed, mean-stationary start-up), which imply that many characteristics are invariant with respect to $3 / 4$ We have set $3 / 4=0: 1$.

Table 5.5 contains results for $T=20$ and 5.6 for $T=50$ : N otice that the coe $\pm$ cient bias is more serious here, and that the reduction by correction is substantial, except for, close to the unit circle, where more than $50 \%$ of the bias remains. The standard
degrees of freedom corrected estimator for the least-squares variance is overstating the true variance when, is small, and this is more serious the closer, is to zero and the sample size smaller. For large values of, the standard expression grossly understates the true variance. Bias correction of the coe $\pm$ cient estimate makes its variance larger. However, only for, very close to zero it has a detrimental erect on the e $\pm$ ciency. For moderate values of , an improvement of e $\pm$ ciency can be obtained by bias correction of the coe $\pm$ cient estimator, and the larger, is the higher the gains will be. The standard expression for the least squares variance, although unbiased to ${ }^{-}$rst-order, is not an appropriate estimator of the variance of the bias corrected coe $\pm$ cient estimator, because it is too optimistic (understates). However, the specially designed variance estimator which is second-order unbiased, proves to be reasonably accurate, and hence the results are rather positive about the potentials of , and V (, ) to improve on standard ${ }^{-}$rst-order asymptotic inference. Note that it might be possible to achieve still better results by slightly adapting the implementations of our versions of, and $\mathrm{V}(\mathrm{y})$ : For instance, , and $\mathrm{V}($,$) could be made even less biased possibly, by$ not taking $\hat{C}$ in the respective formulas, but by iterating at least once and using C (the same for $\hat{Z}$ ): Also $3 / 4$ could be estimated on the basis of residuals obtained by employing, ; etc. We plan to examine the e®ects of these factors in simulations yet to be executed.

The above examination should be extended to more general models including some other exogenous explanatory variables. This will be undertaken in a next version of the paper.

## 6. Conclusions

By adapting and extending techniques we employed in some recent papers to approximate to an accuracy of order $O\left(\mathrm{~T}^{\mathrm{i}}{ }^{2}\right)$ the bias of the least-squares estimators for all the parameters (both coe $\pm$ cients and disturbance variance) in linear regression models with a lagged dependent explanatory variable, we ${ }^{-}$nd here an approximation to the same order for the mean squared error and for the true variance of the least-squares coe $\pm$ cient estimator. For the latter approximation we ${ }^{-}$nd that its algebraic expression di Rers substantially from an approximation to the same order of accuracy for the expectation of the expression that is usually employed to estimate the variance on the basis of standard asymptotic reasoning. This means that the usual estimator, although asymptotically valid, has a bias in ${ }^{-}$nite samples that can be assessed by estimating the expression derived in this paper. Its substraction from the standard expression will yield a less biased variance estimator. In that way the analytic results presented in this paper can be of use for producing new methods to improve the accuracy of inference in ${ }^{-}$nite samples of dynamic regression models. Numerical analysis can be undertaken to produce insight into the seriousness of the - nite sample inaccuracies of ${ }^{-}$rst-order asymptotic expressions for second moments and also into the ability of the higher-order asymptotic analytical approximations to assess and to correct such
discrepancies.
In simple AR (1) models we - nd that there seems certainly scope for such improved procedures, because the standard coe $\pm$ cient variance estimator may understate the true variance of the least-squares estimator by some 30 or $40 \%$, whereas the bias corrected variance estimator is almost unbiased.

The same techniques are also used to approximate the variance of bias corrected coe $\pm$ cient estimators and to develop accurate estimators for the variance of such corrected estimators. Because the bias correction does not a®ect the leading term of the asymptotic variance of the (corrected) coe $\pm$ cient estimator, the standard formula can still be used, because it is asymptotically valid. However, the higher-order asymptotic approximations derived here enable the assessment of more accurate (bias corrected) variance estimators, and also produce analytical insight into the potential e $\pm$ ciency gains or losses due to bias correction. We - nd a strong result for AR(1) models regarding the scope for e $\pm$ ciency improvement. That scope seems to increase with the number of exogenous regressors in the model. The relative magnitude of e $\pm$ ciency gains is shown to be non-monotonic in the sample size. Hence, bias correction may be more erective from an e $\pm$ ciency point of view when the sample size is moderate than in smaller samples, where the coe $\pm$ cient bias is usually larger, simply because a moderate coe $\pm$ cient bias can be assessed more accurately than a huge bias. We also obtain a strong result for the e®ect on e $\pm$ ciency of di Rerent implementations of coe $\pm$ cient bias correction, and - nd that an approach adopted earlier by a good many researchers is sub-optimal from a theoretical point of view.

## A. Some auxiliary results

To prove the results of this paper, we have to obtain the expectation of numerous expressions of various forms, which involve products of up to four quadratic forms in normal variables. In this appendix we state some basic results which are used repeatedly in the subsequent analysis.

Let $A$ be a symmetric $T £ T$ matrix and $B_{1}$ and $B_{2}$ arbitrary $T £ T$ matrices. Let the $T £ 1$ random vector " be such that " » $N\left(0 ; 3 / 4 I_{T}\right)$, then the following results hold:

$$
\begin{align*}
& E\left(" \mathrm{~B}_{1} "\right)\left(" \mathrm{~B}_{2} "\right)={ }^{3 / 4}\left[\operatorname{tr}\left(\mathrm{~B}_{1}\right) \operatorname{tr}\left(\mathrm{B}_{2}\right)+\operatorname{tr}\left(\mathrm{B}_{1} \mathrm{~B}_{2}\right)+\operatorname{tr}\left(\mathrm{B}_{1} \mathrm{~B}_{2}^{0}\right)\right] ; \tag{A.1}
\end{align*}
$$

$$
\begin{align*}
& E\left(" " B_{1} " " 9=E\left(" B_{1} "\right) " n=3 / 4\left[\operatorname{tr}\left(B_{1}\right) I_{T}+B_{1}+B_{1}^{0}\right] ;\right.  \tag{A.3}\\
& E\left(" \mathrm{~A}^{\prime}\right) \mathrm{Q}_{\mathrm{j}=1}\left(\mathrm{"B} \mathrm{~B}_{\mathrm{j}} "\right)=  \tag{A.4}\\
& 3 / 4\left[\operatorname{tr}(\mathrm{~A}) \operatorname{tr}\left(\mathrm{B}_{1}\right) \operatorname{tr}\left(\mathrm{B}_{2}\right)+\operatorname{tr}(\mathrm{A}) \operatorname{tr}\left(\mathrm{B}_{1} \mathrm{~B}_{2}\right)+\operatorname{tr}(\mathrm{A}) \operatorname{tr}\left(\mathrm{B}_{1} \mathrm{~B}_{2}^{0}\right)\right. \\
& +2 \operatorname{tr}\left(\mathrm{~B}_{1}\right) \operatorname{tr}\left(\mathrm{AB}_{2}\right)+2 \operatorname{tr}\left(\mathrm{~B}_{2}\right) \operatorname{tr}\left(\mathrm{AB}_{1}\right)+2 \operatorname{tr}\left(\mathrm{AB}_{2} \mathrm{~B}_{1}\right) \\
& \left.+2 \operatorname{tr}\left(A B_{2}^{0} B_{1}\right)+2 \operatorname{tr}\left(A B_{1} B_{2}\right)+2 \operatorname{tr}\left(A B_{1} B_{2}^{0}\right)\right] ;
\end{align*}
$$

$$
\begin{align*}

& +4\left[\operatorname{tr}\left(A B_{1}\right)\right]^{2}+8 \operatorname{tr}\left(A A B_{1} B_{1}\right)+4 \operatorname{tr}\left(A A B_{1}{ }_{1} B_{1}\right) \\
& +4 \operatorname{tr}\left(A A B_{1} B_{1}^{0}\right)+4 \operatorname{tr}\left(A B_{1} A B_{1}\right)+4 \operatorname{tr}\left(A B_{1} A B_{1}^{0}\right) g:
\end{align*}
$$

M ost of these results are also given in K P (1998a, 1998b). Result (A.1) is obtained upon substituting " $\left.\mathrm{B}_{2} "=" q \frac{1}{2}\left(\mathrm{~B}_{2}+\mathrm{B}_{2}^{0}\right)\right] "=" \mathrm{~A}_{2} "$; where $\mathrm{A}_{2}$ is symmetric, in (A.1) of K P (1998a). This substitution also enables one to prove (A.4) from K P (1998a, A.5), and (A.9) from KP (1998a, A.8) and (A.10) from KP (1998a, A.11). Result (A.2) follows from (A.1) and from $E\left(" B_{1} "\right)=\operatorname{tr}\left(B_{1}\right)$. The proof of (A.3) is given in KP (1998a). Result (A.5) follows easily from (A.4). Results (A.6), (A.7) and (A.8) can be found in KP (1998a). Finally (A.11) follows easily from (A.10).

## B．An approximation to V （ © ${ }^{\text {（ }}$

For the variance V （ ${ }^{(8)}$ ）of the least－squares estimator © ${ }^{\text {© }) ~ w e ~ h a v e ~}$

We want to approximate this to the order of $O\left(T^{i^{2}}\right)$ ：We shall make use of

$$
\begin{align*}
z q & =之 q+z q  \tag{B.2}\\
& \left.\left.=之 q 0: 1_{T}\right] v+e_{1} v q q 9: 1_{T}\right] v \\
& \left.=之 q 0: 1_{T}\right] v+(v q H v) e_{1}=O_{p}\left(T^{1=2}\right)
\end{align*}
$$

where H is the non－symmetric matrix

$$
\begin{equation*}
\left.H=G 90: 1_{T}\right] . \tag{B.3}
\end{equation*}
$$

For H we ${ }^{-}$nd the useful results

$$
\begin{align*}
\operatorname{tr}(\mathrm{H}) & =\operatorname{tr}\left(\left[0: \mathrm{I}_{\mathrm{T}}\right]^{0} \mathrm{G}\right)=\operatorname{tr}\left(\mathrm{G}\left[0: \mathrm{I}_{\mathrm{T}}\right] 9=\operatorname{tr}(\mathrm{C})=0\right.  \tag{B.4a}\\
\operatorname{tr}(\mathrm{HH}) & =0  \tag{B.4b}\\
\operatorname{tr}(\mathrm{H} \mathrm{H}) & =\operatorname{tr}\left(\mathrm{G}^{0} \mathrm{G}\right)  \tag{B.4c}\\
\mathrm{G}\left(\mathrm{H}+\mathrm{H} 9\left[0: \mathrm{I}_{\mathrm{T}}\right]^{0}\right. & =\mathrm{GG}^{0}+\mathrm{CC}: \tag{B.4d}
\end{align*}
$$

The ${ }^{-}$rst term of（B．1）is M SE（B）：For this we ${ }^{-}$nd

We ${ }^{-}$rst develop an expansion of $(Z Z)^{1}{ }^{1}$ ：Referring to（2．7）and（2．8）we have $E\left(Z^{\circ} Z\right)=Q^{i 1}=\dot{Z}^{\circ} Z+E\left(Z^{0} Z^{\prime}\right)$ ，and so

$$
\begin{align*}
& \left.Z Z^{0}=(\bar{Z}+Z)^{9} \bar{Z}+Z \bar{Z}\right)  \tag{B.6}\\
& =E\left(Z^{0} Z\right) i E\left(Z^{0} Z\right)+z^{O} Z+Z^{0} Z+Z^{0} Z \\
& =I_{k+1}+\left(Z^{0} Z+z^{0} Z^{2}\right) Q+\left[z^{0} Z_{i} E\left(z^{0} Z\right)\right] Q^{i} Q^{i 1} \text { : }
\end{align*}
$$

Hence，

$$
\begin{equation*}
\left(Z^{0} Z\right)^{i 1}=Q^{h} I_{k+1}+\left(Z^{0} Z+Z^{0} Z\right) Q+\left[Z^{0} Z i E\left(Z^{0} Z\right)\right] Q^{i_{i 1}} ; \tag{B.7}
\end{equation*}
$$

where the stochastic terms $\left(Z^{0} Z+Z^{0} Z^{\prime}\right) Q$ and $\left[Z^{0} Z ; E\left(Z^{0} Z\right)\right] Q$ are both $O_{p}\left(T^{i=2}\right)$ ． The inverse matrix of the form $\left[I_{n}+A\right]^{i 1}$ ，with $A=O_{p}\left(T^{i}{ }^{1=2}\right)$ an $n £ n$ matrix，may be expanded in $\left[I_{n}\right.$ i $A+A^{2}$ i $\left.A^{3}+:::\right]$ ，whereby successive terms are of decreasing
order in probability. The expansion retains terms up to a certain order and in this way an expansion is obtained which includes terms up to any desired order. For an expansion of $\left(\mathrm{Z}^{\mathrm{O}}\right)^{\mathrm{i}}{ }^{1}$ to order $\mathrm{T}^{\mathrm{i}}{ }^{2}$ we require

$$
\begin{aligned}
& \left(Z^{0} Z\right)^{i 1}=Q^{1} Q^{i 1}{ }^{1}\left(Z^{O} Z+Z^{O} Z^{1}\right)
\end{aligned}
$$

$$
\begin{aligned}
& +\left(z^{0} z+z^{0} z^{2}\right) Q\left[z^{0} Z ; E\left(z^{0} z\right)\right]+\left[z^{0} z_{i} \quad E\left(z^{0} z\right)\right] Q\left(z^{0} z+z^{0} z^{0}\right) \\
& +\left[Z^{0} Z_{i} E\left(Z^{0} Z\right)\right] Q\left[Z^{0} Z_{i} E\left(Z^{0} Z^{2}\right)\right] g Q+o_{p}\left(T^{i^{2}}\right) \text {; }
\end{aligned}
$$

whereas the expansion to order $\mathrm{T}^{i 3=2}$ amounts to

$$
\begin{equation*}
\left(Z^{0} Z^{i 1}=Q ; Q\left(Z^{0} Z+Z^{0} Z\right) Q ; Q\left[Z^{0} Z ; \quad E\left(Z^{0} Z\right)\right] Q+o_{p}\left(T^{i 3=2}\right) ;\right. \tag{B.9}
\end{equation*}
$$

and to order $\mathrm{T}^{\mathrm{i}}$ we simply have

$$
\begin{equation*}
\left(Z^{0} Z\right)^{i 1}=Q+o_{p}\left(T^{i 1}\right): \tag{B.10}
\end{equation*}
$$

The expansion (B.8) for $(Z Z)^{i 1}$ can be written as

$$
\begin{equation*}
\left(Z^{O}\right)^{i 1}=Q\left[I_{k+1} i W_{1} i W_{2}+W_{1} W_{1}+W_{1} W_{2}+W_{2} W_{1}+W_{2} W_{2}\right]+o_{p}\left(T^{i}{ }^{2}\right) \tag{B.11}
\end{equation*}
$$

where we introduced some further shorthand notation, viz.

$$
\begin{align*}
W_{1} & =\left(Z^{0} Z+z^{0} \mathcal{Z}\right) Q  \tag{В.12}\\
& =Z^{0} G v q_{1}^{0}+e_{1} v^{0} G Z Q=O_{p}\left(T^{i 1=2}\right)
\end{align*}
$$

and

$$
\begin{align*}
W_{2} & =\left[Z^{0} \mathcal{Z}_{i} E\left(Z^{0} \bar{Z}\right)\right] Q  \tag{B.13}\\
& =\left[v^{0} G{ }^{0} G v_{i}^{3 / 4} \operatorname{tr}\left(G^{0} G\right)\right] e_{1} q_{1}^{0}=O_{p}\left(T^{i 1=2}\right):
\end{align*}
$$

Note that after premultiplication by Q we have seven terms in (B.11). Of these the ${ }^{-} r$ st is $\left.O\left(T^{i}\right)^{1}\right)$; the second and the third are $O_{p}\left(T^{i 3=2}\right)$; and the remaining four are all $\mathrm{O}_{\mathrm{p}}\left(\mathrm{T}^{\mathrm{i}^{2}}\right)$ : T his yields the following expansion:

$$
\begin{align*}
& \left(B_{i} ®^{\circledR}\right)\left(®_{i} ®^{\circledR}\right)^{0}=\left(Z^{0} Z\right)^{i} Z^{q} u^{0} Z\left(Z^{0} Z^{i}\right)^{1}  \tag{B.14}\\
& =Q Z Q u Z Q \\
& \text { i } Q\left[W_{1}+W_{2} i\left(W_{1}+W_{2}\right)^{2}\right] Z Q u{ }^{\circ} Z Q \\
& \text { i QZqu'Z }\left[W_{1}^{0}+W_{2}^{0} i\left(W_{1}^{0}+W_{2}\right)^{2}\right] Q \\
& +Q\left(W_{1}+W_{2}\right) Z q u^{\circ} Z\left(W_{1}^{0}+W_{2}\right) Q+o_{p}\left(T^{i}{ }^{2}\right) \\
& =Q Z q u Z Q ; Q W_{1} Z Q u Z Q ; Q W_{2} Z Q u^{\circ} Z Q \\
& +Q\left(W_{1}+W_{2}\right)^{2} Z q u u^{0} Z ; Q Z Q u u^{0} Z W_{1}^{0} Q \\
& \text { i } Q Z q u^{0} Z W_{2}^{0} Q+Q Z q u Z\left(W_{1}^{0}+W_{2}\right)^{2} Q \\
& +Q W_{1} Z q u u^{0} Z W_{1}^{0} Q+Q W_{1} Z Q u^{0} Z W_{2} Q Q \\
& +Q W_{2} Z q u u^{\circ} Z W_{1}^{Q} Q+Q W_{2} Z q u u^{0} W_{2}^{Q} Q+o_{p}\left(T^{i}\right)^{2} \text { : }
\end{align*}
$$

Note that

$$
\begin{align*}
& \left.\left.\left.=z 90: 1_{T}\right] v v 90: 1_{T}\right]^{03}+z 90: 1_{T}\right] v(v 9 \mathrm{v}) \mathrm{e}_{1}^{0}  \tag{B.15}\\
& \left.+(\mathrm{v} \mathrm{H} v) \mathrm{e}_{1} \mathrm{v} 90: \mathrm{I}_{\mathrm{T}}\right]^{03}+(\mathrm{v} 9 \mathrm{H} \mathrm{v})^{2} \mathrm{e}_{1} \mathrm{e}_{1}^{0} \text { : }
\end{align*}
$$

We now derive the expectation of the eleven terms of (B.14). For the ${ }^{-}$rst one we obtain

$$
\begin{aligned}
& \left.\left.E\left(Q Z q u Z^{0} Z Q\right)=E Q z q 0: I_{T}\right] v v 90: I_{T}\right]^{0} Q Q+E Q\left(v^{9} H v\right)^{2} e_{1} e_{1}^{0} Q \\
& =3 / 4 Q^{2} Z^{O} Q+3 / 4 \operatorname{tr}\left(G^{0} G\right) Q e_{1} e_{1}^{0} Q \\
& =3 / 4 \mathrm{Q} \text { : }
\end{aligned}
$$

For the expectation of the second term of (B.14) we ${ }^{-}$nd:

$$
\begin{align*}
& \text { E (QW } \left.{ }_{1} Z q^{q} u^{\circ} Z Q\right) \tag{B.16}
\end{align*}
$$

$$
\begin{aligned}
& =Q^{-1} G E\left(v^{9} H v v^{9}\left[0: I_{T}\right]^{3} Z q_{1} q_{1}^{0}+q_{11} Q^{Z} G E\left(v v^{9} H v^{9}\left[0: I_{T}\right]^{03} Q\right.\right.
\end{aligned}
$$

$$
\begin{aligned}
& =3 / 4{ }^{4} Q^{\frac{1}{Z}} G\left(H+H 9\left[0: 1_{T}\right]^{0}{ }^{3} q_{1} q_{1}^{0}+3 / 4^{4} q_{11} Q^{\frac{1}{2}}{ }^{q} G\left(H+H 9\left[0: 1_{T}\right]^{03} Q\right.\right. \\
& +3 / 4 q_{1} q_{1}^{0-2}{ }^{0} G\left(H+H 9\left[0: I_{T}\right]^{0} Z Q+3 / 4 \operatorname{tr}\left(G^{0} Z^{2} Q 之{ }^{2} q_{0}: I_{T}\right][H+H 9) q_{1} q_{1}^{0}\right. \\
& =3 / 4{ }^{4} Q^{\frac{1}{Z}}\left(G^{0}+C C\right) \vec{Z} q_{1} q_{1}^{0}+3 / 4 q_{11} Q^{3} Z^{0}\left(G G^{0}+C C\right) \vec{Z} Q
\end{aligned}
$$

The expectation of the third term of (B.14) is:

$$
\begin{aligned}
& \text { E (QW } \left.{ }_{2} Z q u{ }^{\circ} \mathrm{Z} Q\right) \\
& \left.\left.=E\left[v^{0} G{ }^{9} G v i^{3 / 4} \operatorname{tr}\left(G^{0} G\right)\right] q_{1} q_{1}^{0} \mathcal{Z}^{9} 0: I_{T}\right] v v v^{0} 0: I_{T}\right]^{0} Z Q \\
& +E\left[v^{\circ} G^{\circ} G v i^{3 / 2} \operatorname{tr}\left(G^{0} G\right)\right] q_{1} q_{1}^{0}\left(v{ }^{9}-v\right)^{2} \mathrm{e}_{1} e_{1}^{0} \mathrm{Q} \\
& \left.=2^{3} / 4^{4} q_{1} q_{1}^{0} \mathcal{Z}^{9} 90: 1_{T}\right] G{ }^{0} G\left[0: I_{T}\right]^{0} Z Q \\
& +23 / 4 q_{11}\left[2 \operatorname{tr}\left(G^{\circ} G H H\right)+\operatorname{tr}\left(G^{9} G H 9\right)+\operatorname{tr}\left(G^{9} G H H{ }^{9}\right] q_{1} q_{1}^{0}\right. \\
& =23 / 4 q_{1} q_{1}^{0} Z^{\circ} C^{\circ} C \mathcal{Z} Q \\
& +2^{3} / 4^{6} q_{11}\left[2 \operatorname{tr}\left(G^{9} G C C\right)+\operatorname{tr}\left(G^{0} C^{0} C G\right)+\operatorname{tr}\left(G^{0} G G^{0} G\right)\right] q_{1} q_{1}^{0} \text {; }
\end{aligned}
$$

For the fourth term of (B.14) we have:

$$
\begin{align*}
& E\left[Q\left(W_{1}+W_{2}\right)^{2} Z q u^{0} Z Q\right]=  \tag{B.18}\\
& E\left(Q W_{1} W_{1} Z q u^{0} Z Q\right)+E\left(Q W_{1} W_{2} Z q u^{\circ} Z Q\right) \\
& +E\left(Q W_{2} W_{1} Z q u^{\circ} Z Q\right)+E\left(Q W_{2} W_{2} Z q u^{0} Z Q\right):
\end{align*}
$$

We examine these four terms separately. First we have

$$
\begin{aligned}
& E\left(Q W_{1} W_{1} Z Q u^{\circ} Z Q\right) \\
& =E\left[Q\left(Z^{\circ} G v q_{1}^{0}+e_{1} v^{Q} G Q^{O} Q\right)\left(Z^{0} G v q_{1}^{0}+e_{1} v^{0} G^{O} Z^{-1} Q\right) Z Q u u^{0} Z Q\right]
\end{aligned}
$$

$$
\begin{aligned}
& +23 / 4 q_{11} \operatorname{tr}\left(G^{\circ} G\right) Q Z^{0} G G^{0} Z^{2} q_{1} q_{1}^{0} \\
& +4^{3 / 6} q_{11} Q^{-1} G^{0} G^{0} C^{0} C^{0}{ }^{3} q_{1} q_{1}^{0}+43 /{ }^{3} q_{11} Q^{-}{ }^{0} G C G C{ }^{0} Z q_{1} q_{1}^{0} \\
& +43 / 4{ }^{6} q_{11} Q^{-}{ }^{0} G^{0} G^{0} Z^{0} q_{1} q_{1}^{0}+43 / 4{ }^{6} q_{11} Q^{2} Z^{0} C \text { GG }{ }^{0} q_{1} q_{1}^{0} \\
& +3 / 44^{4} q_{11} \operatorname{tr}\left(Q^{-1} C \bar{Z}\right) Q Z^{c} C \bar{Z} Q
\end{aligned}
$$

$$
\begin{aligned}
& +3 / 4{ }^{6} q_{11} \operatorname{tr}\left(Q^{-1}{ }^{\circ} G G O\right) \operatorname{tr}\left(G^{0} G\right) q_{1} q_{1}^{0}+43 / 4 q_{11} \operatorname{tr}\left(Q^{2} Z^{\circ} C G G O\right) q_{1} q_{1}^{0} \\
& +23 / 8 q_{11} \operatorname{tr}\left(Q^{3}{ }^{0} G C G C O Z\right) q_{1} q_{1}^{0}+23 / 8 q_{11} \operatorname{tr}\left(Q^{2} G^{0} G^{0} G G^{0}\right) q_{1} q_{1}^{0}
\end{aligned}
$$

$$
\begin{aligned}
& +3 / 4\left(q_{1}^{0} z^{0} G G^{0} q_{1}\right) \operatorname{tr}\left(G^{0} G\right) q_{1} q_{1}^{0}+43 / /^{6}\left(q_{1}^{0} z^{0} C^{\circ} \text { CGG }^{0} Z_{1}\right) q_{1} q_{1}^{0} \\
& +2^{3 / 6}\left(q_{1}^{0} \mathcal{Z}^{0} G C G C{ }^{0} q_{1}\right) q_{1} q_{1}^{0}+2^{3 / 4}\left(q_{1}^{0} Z^{0} G G^{0} G G^{0} Z^{1} q_{1}\right) q_{1} q_{1}^{0} \text { : }
\end{aligned}
$$

Various terms are $o\left(T^{i^{2}}\right)$ here. If we remove them, and also use $\bar{Z} \mathcal{Z}^{2} Q=1 i$ $3 / 4 \operatorname{tr}\left(G^{0} G\right) e_{1} q_{1}^{0}$ we obtain

$$
\begin{aligned}
& \mathrm{E}\left(\mathrm{QW} \mathrm{~F}_{1} \mathrm{~W}_{1} \mathrm{Zqu} u^{\circ} \mathrm{ZQ}\right)
\end{aligned}
$$

$$
\begin{aligned}
& +3 / 44 \operatorname{tr}\left(Q^{3}{ }^{0} G G O\right) q_{1} q_{1}^{0}+3 / 4 \operatorname{tr}\left(Q^{-} Z^{0} C Z\right) q_{1} q_{1}^{0} Z^{0} C Z Q+3 / 4 q_{1} q_{1}^{0} Z^{0} G G^{0}{ }^{0} Q
\end{aligned}
$$

For the second term of (B.18) we ${ }^{-}$nd (we immediately remove terms of small order):

$$
\begin{equation*}
E\left(Q W_{1} W_{2} Z Q u^{0} Z Q\right) \tag{B.20}
\end{equation*}
$$

$\left.=E f Q\left(Z^{0} G v q_{1}^{0}+e_{1} v^{0} G^{0} Z^{2} Q\right)\left[v^{0} G^{0} G v i^{3 / 2} \operatorname{tr}\left(G^{0} G\right)\right] e_{1} q_{1}^{0} \mathcal{Z}^{3} q_{0}^{0} I_{T}\right] v\left(v v^{0} v\right) q_{1}^{0} g$

$\left.=q_{11} E f Q Z^{\top} G\left[v^{0} G{ }^{0} G v ;{ }^{3 / 2} \operatorname{tr}\left(G^{G} G\right)\right]\left(v^{9} H v\right) v v^{9} 0: I_{T}\right]^{0} q_{1} q_{1}^{0} g$
$\left.+E f q_{1} q_{1}^{0} z^{0} G\left[v^{0} G{ }^{0} G v ; \quad 3 / 4 \operatorname{tr}\left(G^{0} G\right)\right]\left(v^{9} H v\right) v v^{9} 0: I_{T}\right]^{0}{ }^{0} q_{1} q_{1}^{0} g$
$\left.+q_{11}^{2} E f Q Z^{0} G\left[v^{0} G{ }^{0} G v ; \quad 3 / 2 \operatorname{tr}\left(G^{\circ} G\right)\right]\left(v^{9} H v\right) v v^{9} 0: I_{\mathrm{T}}\right]^{03} \mathrm{Qg}$
$=23 / 4 q_{11} \operatorname{tr}\left(G^{0} C\right) Q^{2}{ }^{C} C \mathcal{Z} q_{1} q_{1}^{0}+23 / 6^{6} \operatorname{tr}\left(G^{C} C\right)\left(q_{1}^{0} 0^{C} C \frac{Z}{Z} q_{1}\right) q_{1} q_{1}^{0}$
$+23 / 4 q_{11}^{2} \operatorname{tr}\left(G^{0} C\right) Q Z^{0} C \mathcal{Z} Q+23 / 4 q_{11} \operatorname{tr}\left(G^{0} C\right) q_{1} q_{1}^{0} \mathcal{Z}^{0} C Z Q+o\left(T^{i}\right)$

Next we examine the third term of (B.18). We ${ }^{-}$nd

$$
\begin{aligned}
& \mathrm{E}\left(\mathrm{QW}_{2} \mathrm{~W}_{1} \mathrm{Z} \mathrm{Qu}^{\circ} \mathrm{ZQ} \mathrm{Q}\right)
\end{aligned}
$$

$$
\begin{aligned}
& \left.+E f\left[v^{0} G{ }^{0} G v i \quad 3 / 4 \operatorname{tr}\left(G^{\circ} G\right)\right] q_{1} q_{1}^{0}\left(Z^{0} G v q_{1}^{0}+e_{1} v^{0} G{ }^{0} Z Q\right)\left(v^{Q} H v\right) e_{1} v v^{9} 0: I_{T}\right]^{0} Z Q g
\end{aligned}
$$

$$
\begin{aligned}
& \left.+E f\left[v^{\circ} G{ }^{\circ} G v ; \quad 3 / 4 \operatorname{tr}\left(G^{G} G\right)\right] q_{1} q_{1}^{0} z^{\circ} G v q_{1}^{0}\left(v^{q} H v\right) e_{1} v{ }^{9} 0: I_{T}\right]^{0} Z Q g \\
& \left.+E f\left[v^{0} G^{\circ} G v i^{3 / 2} \operatorname{tr}\left(G^{0} G\right)\right] q_{1} q_{1}^{0} e_{1} v^{0} G^{\circ} Z^{2} Q\left(v^{9} H v\right) e_{1} v^{9} 0: 1_{T}\right]^{0} Z Q g
\end{aligned}
$$

$$
\begin{aligned}
& =23 / 4 \operatorname{tr}\left(G^{\circ} C\right)\left(q_{1}^{0} Z^{\circ} C Z^{-1} q_{1}\right) q_{1} q_{1}^{0}+23 / 4 q_{11} \operatorname{tr}\left(G G^{0} C\right) \operatorname{tr}\left(Q^{3}{ }^{\circ} C \bar{Z}\right) q_{1} q_{1}^{0} \\
& \left.+43 / 8 q_{11} \operatorname{tr}\left(G^{C} C\right) q_{1} q_{1}^{0} \mathcal{Z}^{C} C \mathcal{Z} Q+o\left(T^{i}\right)^{2}\right):
\end{aligned}
$$

For the fourth term of (B.18) we ${ }^{-}$nd

$$
\begin{aligned}
& \mathrm{E}\left(\mathrm{QW}_{2} \mathrm{~W}_{2} Z \mathrm{Zu}^{0} \mathrm{Z} Q\right)
\end{aligned}
$$

$$
\begin{aligned}
& +q_{11}^{2} E \quad\left[v^{\circ} G{ }^{\circ} G v i^{3 / 4} \operatorname{tr}\left(G^{0} G\right)\right]^{2}\left(v{ }^{9}-v\right)^{2} q_{1} q_{1}^{0}
\end{aligned}
$$

$$
\begin{aligned}
& +23 / 8 q_{11}^{2} \operatorname{tr}\left(G^{Q} G\right) \operatorname{tr}\left(G^{0} G^{0} G\right) q_{1} q_{1}^{0}+83 / 8 q_{11}^{2} \operatorname{tr}\left(G^{0} C\right) \operatorname{tr}\left(G^{0} C\right) q_{1} q_{1}^{0}+o\left(T^{i}{ }^{2}\right) \\
& =23 /{ }^{6} q_{11} \operatorname{tr}\left(G^{0} G^{\circ} G\right) q_{1} q_{1}^{0} Z^{\circ}{ }^{\circ} Q+23 / 8 q_{11}^{2} \operatorname{tr}\left(G^{0} G\right) \operatorname{tr}\left(G^{0} G^{0} G\right) q_{1} q_{1}^{0} \\
& +83 / 8 q_{11}^{2} \operatorname{tr}\left(G^{\circ} C\right) \operatorname{tr}\left(G^{\circ} C\right) q_{1} q_{1}^{0}+o\left(T^{i^{2}}\right) \\
& =23 / 4 q_{11} \operatorname{tr}\left(G^{0} G^{0} G\right) q_{1} q_{1}^{0}+83 / 8 q_{11}^{2} \operatorname{tr}\left(G^{0} C\right) \operatorname{tr}\left(G G^{0} C\right) q_{1} q_{1}^{0}+o\left(T^{i^{2}}\right):
\end{aligned}
$$

Collecting the four terms we ${ }^{-}$nd for ( $B .18$ ), which is the expectation of the fourth term of (B.14):

$$
\begin{equation*}
E\left[Q\left(W_{1}+W_{2}\right)^{2} Z q u Z Q\right] \tag{B.23}
\end{equation*}
$$

$$
\begin{aligned}
& +3 / 4 \operatorname{tr}\left(Q^{0} Z^{0} G G^{0}\right) q_{1} q_{1}^{0}+3 / 4 \operatorname{tr}\left(Q^{0} C \bar{Z}\right) q_{1} q_{1}^{0} z^{0} C z Q
\end{aligned}
$$

$$
\begin{aligned}
& +2^{3 / 6} q_{11} \operatorname{tr}\left(G^{\circ} C\right) \operatorname{tr}\left(Q^{2} Z^{\circ} \mathcal{Z}\right) q_{1} q_{1}^{0}+23 / \sigma^{6} q_{11} \operatorname{tr}\left(G^{\circ} G^{\circ} G\right) q_{1} q_{1}^{0} \\
& +83 / 8 q_{11}^{2} \operatorname{tr}\left(G^{\circ} C\right) \operatorname{tr}\left(G^{\circ} C\right) q_{1} q_{1}^{0}+o\left(T^{i}{ }^{2}\right):
\end{aligned}
$$

For the expectation of the - fth term of (B.14) we - nd:

$$
\begin{equation*}
E\left(Q Z q u u^{0} Z W_{1}^{Q} Q\right)=E\left(Q W_{1} Z q u u^{0} Z Q\right)^{0} ; \tag{B.24}
\end{equation*}
$$

which is just the transpose of the result for the second term (B.16). For the sixth term of (B.14) we -nd:

$$
\begin{equation*}
\mathrm{E}\left(\mathrm{Q} Z q_{u} u^{0} W_{2}^{0} Q\right)=E\left(Q W_{2} z q u u^{0} Q\right)^{0} ; \tag{B.25}
\end{equation*}
$$

which follows easily from (B.17). Likewise for the expectation of the seventh term of (B.14) we have

$$
\begin{equation*}
E^{h} Q Z q u Z\left(W_{1}^{0}+W_{2}\right)^{2} Q^{i}=E^{h} Q\left(W_{1}+W_{2}\right)^{2} Z q u u^{0} Q^{i}: \tag{B.26}
\end{equation*}
$$

The expectation of the eighth term of (B.14) is

$$
\begin{aligned}
& E\left(Q W_{1} Z q u u^{0} W_{1}^{0} Q\right)
\end{aligned}
$$

$$
\begin{aligned}
& +E Q\left(Z^{\circ} G v q_{1}^{0}+e_{1} v^{Q} G{ }^{\circ} Q\right)\left(v^{9}+v\right)^{2} e_{1} e_{1}^{0}\left(q_{1} v^{0} G^{O}+Q Z^{0} G v e_{1}^{0}\right) Q \\
& \left.\left.=E Q Z^{\circ} G v q_{1}^{0} Z^{2} 0: I_{T}\right] v v 90: I_{T}\right]^{0} Z_{q_{1}} v^{0}{ }^{0} Z Q
\end{aligned}
$$

$$
\begin{aligned}
& +q_{11}^{2} E Q Z^{0} G v(v q-v)^{2} v^{0} G{ }^{\circ} Q+q_{11} E Q Z^{0} G v(v H v)^{2} q_{1}^{0} Z^{0} G v q_{1}^{0}
\end{aligned}
$$

$$
\begin{aligned}
& +3 / 80_{11}^{2} \operatorname{tr}\left(G^{\circ} G\right) Q Z^{\circ} G G O Q+3 / 8 q_{11} \operatorname{tr}\left(G^{\circ} G\right) Q Z^{\circ} G G{ }^{0} q_{1} q_{1}^{0} \\
& +3 / 8 q_{11} \operatorname{tr}\left(G^{\circ} G\right) q_{1} q_{1}^{2} Z^{0} G G Q Q+3 / 8 \operatorname{tr}\left(G^{\circ} G\right)\left(q_{1}^{0} Z^{0} G G{ }^{0} q_{1}\right) q_{1} q_{1}^{0}+o\left(T^{i}{ }^{2}\right):
\end{aligned}
$$

$$
\begin{equation*}
E\left(Q W_{1} Z q u u^{0} W_{1}^{Q} Q\right) \tag{B.27}
\end{equation*}
$$

For the expectation of the ninth term of (B.14) we - nd

$$
\begin{equation*}
E\left(Q W_{1} Z q_{u} u^{\circ} W_{2}^{0} Q\right) \tag{B.28}
\end{equation*}
$$

$$
\begin{aligned}
& \left.+E Q\left(Z^{0} G v q_{1}^{0}+e_{1} v^{0} G^{0} Q Q\right)\left(v^{O}-v\right) e_{1} v^{9} 0: I_{T}\right]^{0} Z^{2} v^{0} G^{0} G v_{i} 3 / 4 \operatorname{tr}\left(G^{0} G\right) q_{1} q_{1}^{0} \\
& \left.=q_{11} E Q Z^{0} G v q_{1}^{0} Z^{2} 90: I_{T}\right] v\left(v^{9} H v\right)\left[v^{0}{ }^{\circ} G v_{i} 3 / 4 \operatorname{tr}\left(G^{0} G\right)\right] q_{1}^{0}
\end{aligned}
$$

$$
\begin{aligned}
& \left.\left.+q_{11} E Q Z^{0} G v\left(v v^{9} v\right) v^{9} 0: I_{T}\right]^{0} Z^{2} v^{0} G^{0} \mathrm{Gv}_{i} \quad 3 / 4 \operatorname{tr}\left(G^{0} G\right)\right] q_{1} q_{1}^{0}
\end{aligned}
$$

$$
\begin{aligned}
& \left.+E q_{1} q_{1}^{0} z^{0} G v v^{q} v v^{9}\right)\left[v^{0} G{ }^{0} v_{i} \quad 3 / 4 \operatorname{tr}\left(G^{\circ} G\right)\right]\left[0: 1 I_{T}\right]^{0} q_{1} q_{1} q_{1}^{0}
\end{aligned}
$$

$$
\begin{aligned}
& +2^{3 / 3 / 8 t r}\left(G^{\circ} C\right)\left(q_{1}^{0} Z^{0} C Z q_{1}\right) q_{1} q_{1}^{0}+o\left(T^{i}\right):
\end{aligned}
$$

We obtain for the expectation of the tenth term of (B.14)

$$
\begin{equation*}
E\left(Q W_{2} Z q u^{0} Z W_{1}^{0} Q\right)=E\left(Q W_{1} Z q u u^{0} Z W_{2}^{0} Q\right)^{0} ; \tag{B.29}
\end{equation*}
$$

which is just the transpose of the former term. The expectation of the eleventh and - nal term of (B.14) is

$$
\begin{align*}
& \left.\left.=E q_{1} q_{1}^{2}{ }^{2} q_{0}: I_{T}\right] v\left[v^{0} G{ }^{0} v_{i} \quad 3 / 4 \operatorname{tr}\left(G^{0} G\right)\right]^{2} v q_{0}: I_{T}\right]^{0} q_{1} q_{1}^{0}  \tag{B.30}\\
& +q_{11}^{2} E\left[v^{0} G{ }^{0} v_{i} \quad 3 / 4 \operatorname{tr}\left(G^{0} G\right)\right]^{2}\left(v^{9} H\right)^{2} q_{1} q_{1}^{0} \\
& =2^{3 / 8} \operatorname{tr}\left(G^{\circ} G G^{\circ} G\right)\left(q_{1}^{0} Z^{0} q_{1}\right) q_{1} q_{1}^{0}+23 / 8 q_{11}^{2} \operatorname{tr}\left(G^{0} G G^{0} G\right) \operatorname{tr}\left(G^{0} G\right) q_{1} q_{1}^{0} \\
& +83 / 8 q_{11}^{2} \operatorname{tr}\left(\mathrm{GG}^{0}\right) \operatorname{tr}\left(\mathrm{GG}^{0}\right) q_{1} q_{1}^{0}+o\left(\mathrm{~T}^{i}\right) \\
& \left.=23 / 4 q_{11} \operatorname{tr}\left(G^{0} G^{0} G\right) q_{1} q_{1}^{0}+83 / 8 q_{11}^{2} \operatorname{tr}\left(G^{0} C\right) \operatorname{tr}\left(G^{0} C\right) q_{1} q_{1}^{0}+o\left(T^{i}\right)^{2}\right) ;
\end{align*}
$$

where we used $q_{1}^{0}{ }^{2}{ }^{\circ} q_{1}=q_{11} i^{3 / 4} q_{11}^{2} \operatorname{tr}\left(G^{\circ} G\right)$ :
We may now assemble the various contributions to the mean squared error, and obtain after some simpli cation:

$$
\begin{aligned}
& \operatorname{MSE}(\mathbb{B})=\mathrm{E}\left(\mathrm{~B}_{\mathrm{i}} \mathrm{~B}\right)\left(\mathrm{B}_{\mathrm{B}} \mathrm{i}\right)^{0} \\
& =3 / 4 \mathrm{Q}+
\end{aligned}
$$

$$
\begin{aligned}
& +3 / 4 q_{1} q_{1}^{0} z^{0}\left(G G G^{0} \text { CC ; } 2 C^{\circ} C_{i} C^{0} C 9 z Q\right.
\end{aligned}
$$

$$
\begin{aligned}
& +23 / 8_{11}^{2} \operatorname{tr}\left(G^{\circ} C\right) Q z q C+C q^{2} Q
\end{aligned}
$$

$$
\begin{aligned}
& +3 / 8 q_{11}\left[2 \operatorname{tr}\left(G^{\circ} G^{\circ} G\right) ; 8 \operatorname{tr}\left(G^{\circ} G C C\right) ; 4 \operatorname{tr}\left(G^{\circ} C^{\circ} C G\right)\right] q_{1} q_{1}^{0} \\
& +243 / 8 q_{11}^{2} \operatorname{tr}\left(G^{0} C\right) \operatorname{tr}\left(G^{0} C\right) q_{1} q_{1}^{0}+o\left(T^{i}\right) \text { : }
\end{aligned}
$$

From Theorem 2.1 we easily - $n d$ for the squared bias, the second term of (B.1):

$$
\begin{equation*}
\left[E(®) ; ®[E(®) ; \text { ® }]^{0}\right. \tag{B.32}
\end{equation*}
$$

$$
\begin{aligned}
& =3 / 4\left[\operatorname{tr}\left(Q^{-}{ }^{0} C \frac{1}{Z}\right) q_{1}+Q^{-}{ }^{0} C \frac{1}{Z} q_{1}+23 / 4 q_{11} \operatorname{tr}\left(G G^{0} C\right) q_{1}\right] £ \\
& \left.\left[\operatorname{tr}\left(Q^{-1} C Z\right) q_{1}+Q^{2} Z^{0} C Z^{2} q_{1}+23 / 2 q_{11} \operatorname{tr}\left(G G^{0} C\right) q_{1}\right]^{0}+o\left(T^{i}\right)^{2}\right)
\end{aligned}
$$

$$
\begin{aligned}
& +3 / 6 f 4 q_{11} \operatorname{tr}\left(G^{\circ} C\right) \operatorname{tr}\left(Q^{-} Z^{\circ} C Z\right) q_{1} q_{1}^{0} \\
& +2 q_{11} \operatorname{tr}\left(G G^{\circ} C\right)\left[Q Z^{\circ} C Z q_{1} q_{1}^{0}+q_{1} q_{1}^{0-3} C^{\circ}{ }^{\circ} Z Q\right] g \\
& \left.+3 / 8 \mathrm{f} f 4 q_{11}^{2}\left[\operatorname{tr}\left(G^{\circ} C\right)\right]^{2} q_{1} q_{1}^{0} g+o\left(T^{i}\right)^{2}\right):
\end{aligned}
$$

This result has to be subtracted from the MSE approximation (B.31) to ${ }^{-}$nd the required approximation to V ( © B :

## C. An approximation to $E\left[s^{2}\left(Z^{O}\right)^{i 1}\right]$

We require an expansion for $s^{2}$ : For the numerator of this estimator, given in (1.5), we have, upon using (B.10),

$$
\begin{align*}
& =u q_{i} u q(z+Z) Q(Z+Z) Q+o_{p}(1): \tag{C.1}
\end{align*}
$$

First we shall examine an approximation to the expectation of the coe $\pm$ cient variance estimator $3 \not / 4(Z Z)^{i}$ : Note that (C.1) yields for (1.6) the approximation

$$
\begin{equation*}
3 z_{4}^{2}=\frac{1}{T}\left[u_{1} q_{i} u^{0} Z Q \not Q q_{i} u^{0} Z Q Z q_{i} u^{0} Z Q Z Q_{i} u^{0} Z Q Z Z^{Q}\right]+o_{p}\left(T^{i 1}\right): \tag{C.2}
\end{equation*}
$$

This can be exploited to obtain an order $\mathrm{T}^{\mathrm{i}^{2}}$ approximation to

$$
\begin{equation*}
E\left[3 / 4\left(Z^{0} Z\right)^{i^{1}}\right]=E\left[\left(3 / 4 i^{3 / 2}\right)\left(Z^{0} Z\right)^{i}\right]+3 / 4 E\left[\left(Z^{0} Z\right)^{i^{1}}\right] \tag{С.3}
\end{equation*}
$$

by employing (C.2) and an appropriate expansion for ( $\left.Z^{\circ} Z\right)^{\text {i }}$; see (B.9), and next substituting $\mathbb{Z}=G v e_{1}^{0} ; Z^{0} Z_{i} \quad E\left(Z^{0} Z\right)=\left[v^{\circ} G^{G} G v ; 3 / 4 \operatorname{tr}\left(G^{\circ} G\right)\right] e_{1} e_{1}^{0}$ while making use of $u=\left[0: 1_{T}\right] v$ and $v » N\left[0 ; 3 /\left.4\right|_{T+1}\right]$ :

Note that the contribution of the ${ }^{-}$rst right-hand term of (C.3) stems from not knowing $3 / 4$ when estimating V ( $\mathrm{B}^{(8)}$ : It amounts to:

$$
\begin{align*}
& E\left[\left(3 / 4 i^{3} i^{3 / 4}\right)\left(Z^{0} Z\right)^{i 1}\right]  \tag{C.4}\\
& =E\left[\left(\frac{1}{T} u q_{i}{ }^{3 / 4}\right)(Z Z)^{i 1}\right]
\end{align*}
$$

$$
\begin{aligned}
& =i E\left(\frac{1}{T} u q_{i} \quad 3 / 4\right) Q\left[v^{0} G{ }^{0} G v i \quad 3 / 2 \operatorname{tr}\left(G^{0} G\right)\right] e_{1} e_{1}^{0} Q \\
& i \frac{1}{T} E\left(u^{0} \mathcal{Z} Q \mathcal{Z} Q+u^{0} G v e_{1}^{0} Q e_{1} v^{0} G Q\right) Q+o\left(T^{i}{ }^{2}\right) \\
& =i E\left(\frac{1}{T} u^{q} u_{i}{ }^{3 / 2}\right)\left(v^{0} G{ }^{0} G v\right) q_{1} q_{i}^{0} i \frac{1}{T} E\left(u^{0} Z Q Z Z^{2} u+q_{11} u^{0} G v v^{0} G Q\right) Q+o\left(T^{i}{ }^{2}\right)
\end{aligned}
$$

$$
\begin{aligned}
& =i \frac{2}{T}{ }^{3 / 4} \operatorname{tr}\left(C^{0} C\right) q_{1} q_{1}^{0} i \quad \frac{1}{T^{3} / 4}\left[k+1 i{ }^{3 / 4} q_{11} \operatorname{tr}\left(G^{0} G\right)\right] Q \quad i \quad q_{11} \frac{1}{T} 3^{3 / 4} \operatorname{tr}\left(G^{0} G\right) Q+o\left(T^{i^{2}}\right) \\
& =i \frac{2}{T} 3^{4} \operatorname{tr}\left(C^{0} C\right) q_{1} q_{1}^{0} i \frac{k+1}{T} 3^{3 / 4} Q+o\left(T^{i^{2}}\right):
\end{aligned}
$$

An approximation for the second right-hand term of (C.3) can be obtained from (B.8). Note that of the terms in curly brackets the second and the third term have zero mean, while the ${ }^{-}$fth and sixth term involve factors with zero mean and products of an odd number of zero-mean normal random variables. Hence, when expected values are taken these terms may be ignored. We then have

$$
\begin{align*}
& E\left[\left(Z^{O} Z\right)^{i 1}\right]=Q+E\left[Q\left(Z^{0} Z+z^{0} Z\right) Q\left(Z^{1} Z+Z^{0} Z\right) Q\right]  \tag{C.5}\\
& +E f Q\left[Z^{\circ} Z_{i} E\left(Z^{\circ} Z^{2}\right)\right] Q\left[Z^{0} Z_{i} E\left(Z^{\circ} Z^{2}\right)\right] Q g+o_{p}\left(T^{i}\right) \text { : }
\end{align*}
$$

The second term of (C.5) is

$$
\begin{align*}
& =E\left[Q\left(Z^{0} G v e_{1}^{0}+e_{1} v^{0} G^{O} Z\right) Q\left(Z^{0} G v e_{1}^{0}+e_{1} v^{0} G^{\circ} Z\right) Q\right]  \tag{C.6}\\
& =E\left[Q Z^{\circ} G v_{1}^{0} Q Z^{\circ} G v e_{1}^{0} Q\right]+E\left[Q Z^{0} G v e_{1}^{0} Q e_{1} v^{\circ} G^{0} Z Q\right] \\
& +E\left[Q e_{1} v^{\circ} G^{\circ} Z^{2} Z^{\circ} G v_{1}^{0} Q\right]+E\left[Q e_{1} v^{\circ} G^{\circ} Z^{3} Q e_{1} v^{\circ} G^{\circ} Z^{\circ} Q\right] \\
& =E\left[Q Z^{\circ} G v v^{\circ} G{ }^{\circ} Z Q e_{1} e_{1}^{0} Q\right]+q_{11} E\left[Q Z^{\circ} G v v^{\circ} G{ }^{\circ}{ }^{\circ} Q\right] \\
& +E\left[q_{1} v^{0} G^{\circ} Z^{2} Z^{0} G v q_{1}^{0}\right]+E\left[q_{1} e_{1}^{0} Q Z^{\circ} G v v^{0} G{ }^{\circ} Z Q\right] \\
& =3 / 4\left[Q^{2} G^{0} G{ }^{3} q_{1} q_{1}^{0}+q_{11} Q^{Z^{0}} G^{\circ}{ }^{\circ} Q^{2} Q\right. \\
& \left.+\operatorname{tr}\left(Q^{-1} G G^{0}{ }^{3}\right) q_{1} q_{1}^{0}+q_{1} q_{1}^{0} Z^{\circ} G G^{O} Z^{2} Q\right]
\end{align*}
$$

The third term of (C.5) is

$$
\begin{align*}
& \mathrm{EfQ}\left[Z^{\circ} Z_{i} \mathrm{E}\left(Z^{0} Z^{2}\right)\right] Q\left[Z^{0} Z_{i} \mathrm{E}\left(Z^{0} Z^{2}\right)\right] \mathrm{Qg}  \tag{C.7}\\
& =E f Q\left[v^{0} G^{0} G v ; 3 / 2 \operatorname{tr}\left(G^{0} G\right)\right] e_{1} e_{1}^{0} Q\left[v^{0} G^{0} G v ; 3 / 2 \operatorname{tr}\left(G^{0} G\right)\right] e_{1} e_{1}^{0} Q g \\
& =q_{11} E\left[v^{0} G{ }^{\circ} G v i^{3 / 4} \operatorname{tr}\left(G^{\circ} G\right)\right]^{2} q_{1} q_{1}^{0} \\
& =q_{11}\left[E\left(v^{0} G^{0} G v v^{0} G{ }^{\circ} G v\right) ; 2^{3 / 4} \operatorname{tr}\left(G^{0} G\right) E\left(v^{0} G{ }^{0} G v\right)+3 / 4 \operatorname{tr}\left(G^{0} G\right) \operatorname{tr}\left(G^{0} G\right)\right] q_{1} q_{1}^{0} \\
& =23 / 4{ }^{4} q_{11} \operatorname{tr}\left(G^{0} G^{0} G\right) q_{1} q_{1}^{0} \text {. }
\end{align*}
$$

G athering terms yields the result

$$
\begin{align*}
& \left.3 / 4 \mathrm{E}\left[\left(Z^{\circ}\right)^{i}\right)^{1}\right]=3 / 4 Q \tag{С.8}
\end{align*}
$$

$$
\begin{aligned}
& +2^{3 / 6} q_{11} \operatorname{tr}\left(G^{0} G G^{0} G\right) q_{1} q_{1}^{0}+o_{p}\left(T^{i^{2}}\right) \text { : }
\end{aligned}
$$

Adding up the terms (C.4) and (C.8) we obtain the approximation

$$
\begin{aligned}
& \frac{\mathrm{T} \mathrm{i}_{\mathrm{i}} \mathrm{I}_{3 / 2} \mathrm{Q}}{\mathrm{~T}} \\
& +3 / 4 \mathrm{f}\left[\operatorname{tr}\left(Q^{-} Z^{\circ} G G O Z\right) ; \frac{2}{T} \operatorname{tr}\left(C^{\circ} C\right) \mathrm{q}_{1} q_{1}^{0}\right. \\
& +Q Z^{0} G G{ }^{\circ} q_{1} q_{1}^{0}+q_{1} q_{1}^{0} Z^{\circ} G G O Z+q_{11} Q^{\circ} G G O Z g \\
& +2^{3 / 6} q_{11} \operatorname{tr}\left(G^{\circ} G^{9} G\right) q_{1} q_{1}^{0}
\end{aligned}
$$

for $\left.E[3 \not)^{2}(Z Z)^{i}\right]$ : From this the result of Theorem 2.3 follows upon multiplying the above by $T=(T ; k ; 1)$ : This a Rects the leading term, but not the remaining terms to the order of $\mathrm{T}^{\mathrm{i}}$ :

## D. The bias of the COLS estimator

Y et to be typed, and so are the appendices E, F, G.
