Optimal Fiscal Policy in Overlapping Generations Models

Carlos Garriga^{*}

Universitat de Barcelona and CREB

ABSTRACT

This paper analyzes optimal taxation problems in overlapping generation economies with production where agents live I periods. The primal approach is used to characterize the optimal ...scal policy in steady state and along the transition path to some steady state. The key ...ndings is that under certain assumptions (complete set of instruments and separability of the utility function) capital taxes are zero along the transition path to the steady state after two periods. This result is an equivalent version of Chamley (1986) with OG. With additional assumptions it can be shown that non-separable utility functions satisfy the zero capital taxes result in steady state.

[&]quot;I want to thank the useful comments of Juan Carlos Conesa, Tim Kehoe, Dirk Krueger, Antonio Manresa and specially to V.V. Chari and Pat Kehoe without their continuous support this paper would not exist. I also acknowledge the ...nancial support of DGCYT PB96-0988 from Ministerio de Educación and SGR97-180 from Generalitat de Catalunya. I'm fully responsible for the remaining errors. 1. Introduction

This paper analyzes the optimal ...scal policy in overlapping generation economies with production where agents live I periods. The primal approach is used to characterize the optimal taxes in steady state and along the transition path to some steady state. The basic idea is to transform the government problem of choosing the optimal taxes, into a simple programming problem of choosing allocations subject to some constraints.

The key ...ndings is that if the set of taxes is complete and the utility is homothetic and separable, then capital taxes are zero along the transition path to the steady state after two periods. This result is an equivalent version of Chamley (1986) with overlapping generations. With additional assumptions in the discount factor and endowment of e¢ciency units, it can be shown that non-separable utility functions satisfy the zero capital taxes result in steady state, but not during the transition path. This is due to the fact that from the government point of view, under this assumptions, the overlapping generation economy is equivalent to an in...nitely lived economy.

Optimal taxation literature tries to answer how taxes should be set in an e¢cient way (in a constrained e¢cient sense). For this purpose the government is introduced as an active agent in the economy that chooses optimally the ...scal policy according to some objective function. In the last decade the optimal taxation literature, that started with Ramsey (1927) seminal paper, has take over analysis of policy design in macroeconomic models. The primal approach developed by Atkinson and Stiglitz (1980) for static economies and for Lucas and Stokey (1983) for dynamic economies has been very successful for the analysis of the optimal ...scal policy. Most of the recent literature has focused in the optimal ...scal design in in...nitely lived economies, see Chari et al. (1991, 1994 and 1998), Jones, Manuelli and Rossi (1993),

Aiyagari (1995) and others.

The ...rst paper that introduces the optimal taxation problem in a two period overlapping generation economy is Pestieau (1974). He analyzes the optimal ...nancing of a public investment. An important contribution in the framework of the OG model is Atkinson and Sandmo (1980). They study the optimal ...nancing of non-productive public consumption expenditure. In this environment if the government has access to a full set of tax instruments, that include lump-sum taxes, the optimal policy can achieve full ecient allocations. Both papers limit their analysis to steady state solutions. More recently, Escolano (1992) uses an optimal taxation approach to quantify the inecciencies of the ...scal system of the United States economy. He shows that under certain restrictions in the policy instruments, the ...scal system can not be consider as suboptimal, so positive taxes on capital may be optimal. Atkeson et al. (1999) in a two period OG also show that capital taxes are zero in steady state.

The scope of this paper is to provide a general framework for analyzing optimal taxation issues in large economies where agents diverge in their age. As a ...rst step, this paper proofs some results in characterizing the optimal ...scal policy specially along the transition path to some steady state.

The paper is organized as follows. In section 2 we introduce the basic environment and de...ne a competitive equilibrium with distortions. Section 3 describes the government problem of choosing the optimal ...scal policy, and section 4 introduces the primal approach for solving optimal taxation problems. Section 5 derives the zero capital tax for the transition path. Section 6 derives the basic results for the steady state, and section 7 introduces the optimal ...scal problem in an environment with incomplete set taxes. Finally, section 8 concludes.

2. Environment

The model is a standard production economy with two goods, consumption-capital good and leisure. Agents live I periods and each cohort is populated by a continuum of households. For simplicity we assume that population is stationary and its total size is normalize to one.

There is a representative ...rm that produces aggregate output Y_t using a constant returns to scale production function $F(K_t; L_t)$, using capital K_t and labor L_t as primary inputs (measured in e Φ ciency units). This technology is constant returns to scale, monotone, strictly concave and satis...es the Inada conditions. Capital depreciates each period at a constant rate \pm 2 (0;1); there is no exogenous technological change. Competitive factor markets ensure that factors are paid to its marginal product,

(1)
$$r_t = F_{K_t i} \pm$$

(2)
$$W_t = F_{L_t}$$

Households in this economy have standard preferences de...ned over consumption and leisure and are represented by a time separable utility function:

(3)
$$\frac{\mathsf{X}}{\mathsf{I}_{\mathsf{i}}}^{-\mathsf{I}_{\mathsf{i}}} \mathsf{U}(\mathsf{c}_{\mathsf{t}}^{\mathsf{i}}, \mathbf{t}^{\mathsf{i}});$$
 8t

where c_t^i and t_t^i denote consumption and leisure of a household of age i at time t, and t_t^i > 0 is the subjective discount factor. The utility function u(t) is C_t^2 ; strictly increasing in consumption, decreasing in labor, strictly concave and satis...es Inada conditions. The agents are endowed at each period of a unit of divisible time and an age speci...c vector of ecciency units t_t^i = t_t^i = t_t^i that is assumed time invariant. Therefore at each period agents will

decide how much to consume, save, and how many exective units of labor supply to ...rms. Households face a sequence of budget constraints:

(4)
$$a_t^1 = a_t^{1+1} = 0$$
; 8t

(5)
$$(1 + \lambda_{c_{i;t}})c_t^i + a_{t+1}^{i+1} = (1_i \lambda_{i;t})w_t^{2^{i}} + (1 + r_t(1_i \mu_{i;t}))a_t^i$$
 i 2 [1;1]; 8t

the ...rst equation imposes that agents born and die with zero wealth, so agents can not die indebted nor leave bequest. Let r_t be the net return of asset holdings and w_t is the wage rate per e¢ciency units of labor. Households can accumulate wealth a_{t+1}^i in two forms, lending capital to ...rms and buying government debt of one period maturity. Let $\lambda_{c_1,t}$; $\mu_{k_1,t}$ and $\lambda_{i,t}$ be an age speci...c consumption capital and labor tax respectively. I assume that the government can perfectly discriminate agents by age on their tax payments, and can monitor any side trade done by agents. Therefore, I rule out any possibility of collusion among agents on their investing decisions. Latter on we will see that dropping this assumption and imposing the same taxes to all individuals will have important implications in the optimal policy. Intertemporal trade between generations is allowed. The capital stock and debt at period t=0 is owned by the initial generations.

The government in this economy …nances an exogenous sequence of public expenditure $fG_tg_{t=0}^1$, and redistributes resources between generations using taxes and debt. The government budget constraint is:

¹In order to rule out corner solutions on the investment decisions of households, it is necessary impose a tax on the return of debt. Otherwise agents with low capital tax would invest all their savings in capital and none in debt, and the other way around. With this implicit tax on the return of debt the arbitrage condition will holds for all agents. Abusing notation I will assume that net returns on capital and debt are the same for each generation, but di¤erent across generations.

On the left hand side we have government revenues from age speci...c taxes on consumption, labor and capital and debt; on the right hand side we have government expenditure in public consumption and payroll on debt. The government expenditure is assumed to be a ...xed fraction of output, $G_t = \overline{g}Y_t$: The economy resource constraint is given by:

Definition 1. Let $\%=ff_{\dot{\mathcal{L}}_{c_i;t}}; \mu_{i;t}g^l_{i=1}g^1_{t=0}$ be the in…nite sequence of policies, and let a be the set of all feasible policies. We denote by % a the subset of policies for which competitive equilibrium exists.

Definition 2. Given a policy rule $\frac{1}{2}$; and public consumption $\frac{1}{2}$; a competitive equilibrium for this economy is a sequence of individual allocations $x = \frac{1}{2} \int_{t+1}^{t} g_{t+1}^{l} g_{t+1}^{l$

Notice that we have not imposed the government budget constraint in the de...nition of equilibrium. If all the equilibrium conditions are satis...ed but the government budget constraint, then Walras law ensures that this constraint also is satis...ed.

Given the assumptions of concavity and monotonicity on the functional forms the ...rst-order conditions are su¢cient to characterize an interior solution.

3. Ramsey Equilibrium

Once we have de...ned a competitive equilibrium we want to focus our attention on the government problem, which has to choose optimally a policy ¼ that maximize society's welfare (the utility of all generations), subject to constraints. This constraints imply, ...rst that the government budget constraint has to be satis...ed in present value. Second, the additional constraint imposes that the optimal policy constitutes a competitive equilibrium with distortionary taxes. I assume that the government has access to a commitment technology that allows it in period 0; to bind itself choosing a one shot sequence of policies. This kind of commitment technology has been proved that might cause time-consistency problems, as it has been show by Stroz (1957), Kydland and Prescott (1977) and Chari et al. (1986). This is because the government may have incentives to deviate from the optimal policy once it has been announce. When the government does not have access to a commitment technology, it is necessary to design reputation and credible mechanisms to avoid time consistency problems, a reference in this literature are Chari and Kehoe (1990 and 93), Kotliko¤ (1988) and Tabellini (1991). Alternatively Klein and Rios-Rull (1999) have solved the problem with partial commitment. They ...nd that the optimal capital taxes are very similar to the observed in the data.

The Ramsey equilibrium concept treats the government as a dynamic player that takes into account that changes in policies will axect prices, allocations and hence government revenues. Notice that in this type of environment players time horizon does not coincide, while the government is an in...nitely lived player, households live I periods. Given that the government has to foresight agents' behavior is useful to describe allocations and prices using rules.²The reaction function of each agent is useful to understand how individual decisions change under changes in the policy.

²We do not make any assumption of uniqueness or continuity of the allocation rule and the price rule, allowing those be a correspondence. A reference for anomalies in models with taxes and externalities is Kehoe et al. (1992).

Definition 3. An allocation rule $x_{1/4} = x(1/4)$ is a sequence of functions that map policies 1/4 2 | into allocations x: A price rule $r_{1/4} = r(1/4)$; $w_{1/4} = w(1/4)$; $w_{1/4} = w(1/4)$; $w_{1/4} = w(1/4)$ is a sequence of functions that map policies 1/4 2 | into prices $r_{1/4}$; $w_{1/4}$;

If we do not introduce any restriction on the optimal policies, the government has incentives to tax heavily the initial stock of capital. To avoid these problems we assume that the government takes as given the initial taxes on capital stock $f\mu_{i;0}g_{i=1}^I$; and consumption $f_{\hat{\mathcal{C}}_{0;0}}g_{i=1}^I$.

The government is benevolent and values the utility of all households in the economy from period 0 onwards. Its objective function will be the weighted sum of all generations. Therefore the government assigns a non negative weight to all generations. The in…nite sequence is assumed to be bounded above by a positive constant $_i < 1$. Formally ! $_t$ is the weight that the government assigns to the generation born at time t;

(8)
$$W(fc_t^i; \dot{t}^i g) = \frac{\cancel{X}}{t=0} \underbrace{1}_{t=1}^{t} \underbrace{1}_{t+1_i}^{t} \underbrace$$

$$(9) \qquad \underset{t=i \ (l_i \ 1)}{\cancel{X}}!_{t} \cdot i$$

A particular case of this objective function that will be used latter on to derive some important results, imposes an exponential decreasing sequence of weight to all agents. This is important to characterize the optimal ...scal policy in steady state. Given the objective function we can proceed to describe the government problem.

Definition 4. Given an exogenous sequence of public expenditure $fG_tg_{t=0}^1$; a Ramsey equilibrium is a policy k; an allocation rule x_b and a price rule r_b ; w_b ; R_b that satis...es:

(i) The policy 16 solves:

(10)
$$\max_{\frac{1}{4}} \frac{x}{t} \frac{x}{t} \frac{h}{t+1_{i}} \frac{3}{t} U c_{t}^{i}(\frac{1}{4}); \dot{t}^{i}(\frac{1}{4})$$

(ii) The policy 14; the allocation rule $x(\frac{1}{4})$ and the price rule $r(\frac{1}{4})$; $w(\frac{1}{4})$; $R(\frac{1}{4})$ belong to the subset of policies that constitute a competitive equilibrium, $\frac{1}{4}(\frac{1}{4})$:

The concept of Ramsey equilibrium is equivalent to a Nash equilibrium, where the strategies for the government are the policies $14\ 2\ |\$; and households chose x(14) taking as given competitive prices and the ...scal policy.

4. Primal Approach

We will use the primal approach to solve the government problem. The base line is to de...ne a problem of choosing e¢cient allocations subject to some constraints that restrict the allocations to be supported as a competitive equilibrium with distortionary taxes. These constraints are given by feasibility and the implementability constraint. The implementability constraint takes into account that changes in the policy will a¤ect agents' decisions, and is constructed by substituting the ...rst-order conditions of the households and ...rms' problem in consumers budget constraints. Therefore all constraints depend on allocations. The following two propositions show equivalence between this problem and the standard Ramsey equilibrium problem.

Proposition 1. The allocations $x = ffc_t^i$; $t_t^i g_{i=1}^i$; $t_t^i g_{i=2}^i g_{t=0}^i$ in a competitive equilibrium satisfy the resource constraint, and an implementability for each generation. The imple-

mentability constraint for the newborn generations,

and for the initial old generations s [2;1] (the s term will denote the initial generations) at t=0 the implementability constraint has a shorter life-span and the initial endowment of wealth in capital and debt appears on the right hand side, together with the consumption taxes at time zero.

(13)
$$\sum_{i=s}^{s} c_{i_{i} s}^{i} U_{c_{i_{i} s}^{i}} + \sum_{i_{i} s}^{s} U_{c_{i_{i} s}^{i}} = U_{c_{0} s} (a_{0}^{s}; s = 2; ...; 1; s)$$

Proof. Is straightforward to see that any competitive equilibrium by de...nition satis...es the resource constraint. To derive the implementability constraint we ...nd households ...rst-order conditions with respect to c_t^i ; a_{t+1}^i . Assuming an interior solution and being e_t^i the Lagrange multiplier of the intertemporal budget constraint we have:

(14)
$$^{-i}U_{c_t^i} = {}^{\tiny{\textbf{@}}}_t(1 + {}_{c_{i;t}});$$
 8t; i

(15)
$$^{-i}U_{:;} = i \ ^{\otimes}_{t}(1 \ i \ \dot{\mathcal{L}}_{:;t})w_{t};$$
 8t; i

and with respect to $a_{i+1:t+1}$:

(16)
$$\mathbb{R}_{t} = \mathbb{R}_{t+1}(1 + r_{t+1}(1 + \mu_{i+1;t+1}));$$
 8t; i

to derive the implementability constraint we have to multiply (14); (15) with its respective control variable and then add them up, we substitute households budget constraint and using (16) we can eliminate the asset holdings. The resulting expression is the implementability constraint for the new born. The initial old at t = 0 will have a wealth endowment, that appears on the right hand side of the implementability constraint.

In the standard representative agent economies the government only faces one implementability constraint, due to the fact that there is only one agent in the economy that lives in...nite periods. In this case, there are in...nite agents that live a ...nite number of periods, this implies that all agents have their implementability constraint that retects that changes in the policy will a ect their optimal decisions.

Proposition 2. Given the initial allocations and the initial policies, if there is a sequence of allocations that satis...es feasibility and the implementability constraint of all agents we can construct a sequence of policies and prices, that together with the allocations and the price system constitute a competitive equilibrium with distortionary taxes.

Proof. The supporting prices are determine by the ...rms ...rst-order conditions:

(17)
$$r_t = F_{K_t j} \pm;$$
 8t;

(18)
$$W_t = F_{L_t};$$
 8t;

The optimal speci...c taxes from $t \downarrow 0$ can be recovered by using the ...rst-order conditions of the consumers problem and its budget constraint:

(19)
$$\frac{U_{c_{t}^{i}}}{U_{\cdot i}^{*}} = i \frac{(1 + \lambda_{ci;t})}{(1_{i} \lambda_{i;t}^{*}) \ell_{W_{t}}}; \qquad 8t; i$$

(20)
$$\frac{U_{c_{t}^{i}}}{(1+\dot{c}_{c_{i}:t})} = -\frac{U_{c_{t+1}^{i+1}}}{(1+\dot{c}_{c_{i+1}:t+1})} (1+r_{t+1}(1+\mu_{i+1};t+1)); \qquad 8t; i$$

substituting the equilibrium prices fr_t ; w_t ; $fR_{i;t}g_{i=1}^lg_{t=0}^1$ and the optimal allocations x constitute a system of equations from were we can obtain the optimal policy. Notice that if feasibility and the implementability constraint (households' ...rst-order conditions and budget

constraint) are satis...ed, then by Walras law the government budget constraint is also satis...ed. From the consumer budget constraint we obtain the asset holding consistent with prices and taxes. The dimerence between the aggregate level of assets and the capital stock gives the aggregate level of debt.

The optimal policy associated with the Ramsey allocations is not unique, the decentralization of the Ramsey allocation problem is conditioned by set of instruments that are available for the government.

Corollary 1. Given an exogenous sequence of public expenditure $f\overline{g}_tg_{t=0}^1$; the initial distribution of wealth $a_{i;0}$; if $\frac{1}{4}=ff_{\dot{c}_{i;t}}$; $\mu_{i;t}g_{i=1}^1g_{t=0}^1$ is the optimal policy associated to an eccient allocation $x=ffc_t^i$; $i_tg_{i=1}^1$; $fa_{t+1}^ig_{i=2}^1g_{t=0}^1$; then there exists some $\frac{1}{4}=ff_{\dot{c}_{i;t}}$; $\mu_{i;t}^0g_{i=1}^1g_{t=0}^1$ that support the same allocation.

In this case we have redundancy of instruments, because the number of equations at each period is 3 × 1 and the number of instruments is 4 × 1: The redundancy of instruments depends on the number of equations that need to satisfy the equilibrium conditions and the number of ...scal instruments. The primal approach implies implement the wedges between the marginal rates of substitution and marginal rates of transformation, but it does not prescribe any particular type of instruments. This implies that the optimal policy can be supported as a competitive equilibrium under a variety of tax schemes. The unique requirement to decentralize the economy is have a complete set of instruments, that means that there are enough instruments to equate all wedges. We will see later on the implications of relaxing this assumption. For simplicity, the analysis will be restricted to optimal policies where only

taxes on production factors $\% = ff_{\dot{\mathcal{L}}_{i;t}}, \mu_{i;t}g_{i=1}^{1}g_{t=0}^{1}$ and debt B_{t+1} are available.³

Proposition 3. The allocation on the Ramsey equilibrium (RE) solves the Ramsey allocation problem (RAP):

(21)
$$\max_{ffc_{t}^{i}; \hat{t}_{t}^{i}g_{i-1}^{i}; fa_{t+1}^{i}g_{i-2}^{i}g_{t=0}^{1}} \underbrace{\mathbf{X} \mathbf{X}}_{t+1_{i}} \underbrace{\mathbf{h}}_{t+1_{i}} \underbrace{\mathbf{h}}_{t-1_{i}} \underbrace{\mathbf{U} \left(c_{t}^{i}, \hat{t} \right)}_{t} \mathbf{i}$$

(22)
$$x c_{i;t} + K_{t+1} + G_t = F(K_t; L_t) + (1_{i-t})K_t;$$
 8t

where the initial distribution of wealth $a_{s:0}$ for s 2 (2; I) is given.

The main dixerence between those two problems is that the RAP does not depend on taxes and prices. The existence of a solution depends on the properties of the implementability constraint. Except for the implementability constraint, this problem is equivalent to a growth model with a ...nite number of goods. To ...nd a solution, is useful to rede...ne the objective function by introducing the implementability constraint on it, and its associated Lagrange multiplier as co-state variable. Let $\hat{\ }_t$ be the Lagrange multiplier of the implementability constraint for the agent born in period t:⁴

$$(25) \quad V\left(c_{t}^{i}, \dot{t}; \dot{t}\right) = U\left(c_{t}^{i}, \dot{t}\right) + \dot{t}\left(c_{t}^{i}U_{c_{t}^{i}} + \dot{t}^{i}U_{\dot{t}^{i}}\right)$$

³The case where budget balanced is imposed at each period will not be studied in this paper. In this case will be necessary to use consumption taxes, otherwise the set of instruments will be incomplete, see Chari and Kehoe (1998) for a detail explanation.

⁴ See Marcet and Marimon (1998) to see under what conditions we can expand the state space to include the Lagrange multiplier as a co-state variable.

The Ramsey allocation in Lagrangian terms can be written as:

(26)
$$\max_{\mathbf{x}} \underbrace{\mathbf{x}}_{t=0}^{\mathbf{x}} \underbrace{\mathbf{x}}_{t+1_{i}}^{\mathbf{h}} \underbrace{\mathbf{h}_{-i_{i}}^{\mathbf{h}} \mathbf{U}(c_{t}^{i}, i)}_{s=1}^{\mathbf{i}} \underbrace{\mathbf{x}}_{s=2}^{\mathbf{h}} \underbrace{\mathbf{h}_{c_{0}^{s}} \mathbf{h}_{c_{0}^{s}}}_{s=2}^{s}$$

subject to resource constraint. The ...rst-order conditions of an interior solution for this problem at t>0;

(27)
$$\frac{V_{\cdot i}}{V_{c_{t}^{i}}} = i F_{L_{t}} \ell^{2i};$$
 8i; t

(28)
$$!_{t+1_i} V_{c_t^i} = !_{t+2_i} V_{c_{t+1}^i} (1_i \pm F_{K_{t+1}});$$
 8i; t

(29)
$$V_{c_t^i} = {}^- (\frac{1}{t})_{t+1_i} V_{c_t^{i+1}};$$
 81;1

Equation (27) is the intratemporal condition between consumption and labor, note that the V(t) are dimerent objects than the utility function. Equation (28) is the intertemporal condition that says how much capital is going to be invested next period according the government subjective valuation of future generations and the marginal productivity of capital. Equation (29) implies that the planner will assign resources according within two dimerent generation depending on the ratio of relative weight of each generation.

For the s initial generations at t=0; the ...rst-order conditions are slightly dixerent given that the incorporate an additional term. The intratemporal condition:

(30)
$$\frac{V_{0}^{s} i^{\frac{1}{1}} S_{0}^{s} U_{0}^{s} S_{0}^{s} ((1 + r_{0}(1_{i} \mu_{s0})a_{0}^{s}) + U_{0}^{s} F_{K_{0}} S_{0}^{s} (1_{i} \mu_{s0})a_{0}^{s})}{V_{0}^{s} i^{\frac{1}{1}} S_{0}^{s} U_{0}^{s} S_{0}^{s} ((1 + r_{0}(1_{i} \mu_{s0})a_{0}^{s}))} = i^{\frac{1}{1}} F_{L_{0}} \ell^{2s};$$

and the redistributive condition,

$$V_{c_0^s\ i}\ \hat{}_{1_i\ s}U_{c_0^sc_0^s}((1+r_o(1_i\ \mu_{s0})a_0^s) = -\frac{!}{!}_{s}\frac{\textbf{h}}{V_{c_0^{s+1}\ i}}\ \hat{}_{2_i\ s}U_{c_0^{s+1}c_0^{s+1}}\ (1+r_o(1_i\ \mu_{s+1;t})a_0^{s+1}),$$

We also have a transversality condition, but in this case it will not add su⊄ciency because the ...rst-order conditions are only necessary to characterize the optimal solution.

(31)
$$\lim_{t \to 1} {}^{1}_{t} \& K_{t+1} = 0$$

5. Particular Functional Forms

This section characterizes the optimal ...scal policy for some particular functional forms.

Under the assumption of a complete set of ...scal instruments, certain types of utility function satisfy Chamley (1986) result.

Proposition 4. If the utility function is of this type $u(c; `) = \frac{c^{1_i \frac{34}{4}}}{1_i \frac{34}{4}} + h(`)$; it can be shown that is no optimal tax capital accumulation decisions from period 2 onwards.⁵

Proof. In order to proof this result I proceed in two steps. First show that age speci...c capital taxes for the newborns are zero from period 1 onwards, and then that capital taxes for the initial old are zero from period 2 onwards. The Ramsey allocation ...rst-order conditions for the newborns imply:

(32)
$$V_{c_t^i} = {}^-V_{c_{t+1}^{i+1}}(1_{i-t} + F_{K_{t+1}});$$
 $t = 0$

the competitive equilibrium ...rst-order conditions for the newborns are given by:

$$(33) \quad U_{c_t^i} = {}^-U_{c_{t+1}^{i+1}}(1+r_{t+1}(1_{i}\ \mu_{i;t+1})); \qquad 8t$$

⁵Some examples of this utility function that satis...es the initial assumptions can be the followings: (1)

$$U(\emptyset) = \frac{C^{1_{i} \frac{34}{1}} \frac{1}{i} \frac{1}{1}}{1_{i} \frac{34}{1}} + \frac{(1_{i} \frac{1}{i})^{1_{i} \frac{34}{1}} \frac{1}{i} \frac{1}{4}}{1_{i} \frac{34}{1}};$$

notice that if $\frac{3}{4} = \frac{3}{4} = 1$; we have the logarithmic utility function, $U(\mathfrak{l}) = \ln \mathfrak{c} + \ln(1_{\tilde{l}})$; or alternatively, (2)

$$U(\mathfrak{c}) = \frac{c^{1_{i} \cdot \frac{3}{4}_{1}} i \cdot 1}{1_{i} \cdot \frac{3}{4}_{1}} i \cdot a^{*};$$

(3)
$$U(\mathfrak{t}) = \frac{c^{1_{\dot{1}} \frac{3}{4}_{1}} \dot{1}}{1 \dot{1}^{\frac{3}{4}_{1}}} + \frac{1}{1 + \frac{3}{4}_{2}};$$

for this type of utility functions is easy to see that satis...es:

(34)
$$\frac{W_{c_t^i}}{W_{c_{t+1}^{i+1}}} = \frac{U_{c_t^i}}{U_{c_{t+1}^{i+1}}};$$
 8t;

therefore the optimal policy implies set $\mu_{i;t+1}=0$: So is optimal not distort capital accumulation for the newborn generations. Second, I need to show that the s old generation only will have positive taxes on capital on the ...rst period. At t=0; the Ramsey allocation ...rst-order conditions for the initial generations:

(35)
$$\Psi_{c_0^s} = {}^{-}V_{c_1^{s+1}}(1_{i} \pm F_{K_1});$$
 s 2 (2; I i 1)

where $\Psi_{c_0^s} = V_{c_0^s i} \hat{I}_{1i s} U_{c_0^s c_0^s} \hat{R}_{s0}^k k_0^s + \hat{R}_{s0}^b b_0^s$: The competitive equilibrium intertemporal equation imply:

(36)
$$U_{c_0^s} = U_{c_1^{s+1}}(1 + r_1(1_i \mu_{s;1}));$$
 s 2 (2; I i 1)

Notice that there are s initial old, but only I $_{\rm i}$ 2 have saving decisions. This type of utility function does not satisfy:

(37)
$$\frac{\Psi_{c_0^s}}{V_{c_0^{s+1}}} \in \frac{U_{c_0^s}}{U_{c_0^s}};$$
 s 2 (2; I i 1)

Hence the initial generations at t=0 will have $\mu_{s;1}$ \in 0; but at t=1 the Ramsey intertemporal imply,

(38)
$$V_{c_1^s} = {}^{-}V_{c_2^{s+1}}(1_{i} \pm F_{K_2});$$
 s 2 (2; I_{i} 2)

Hence $\mu_{s;2} = 0$: From this point onwards age speci...c capital taxes are zero for all agents.

This implies that from period t _ 2; capital taxes will be zero for all agents, and di¤erent from zero in period 1: The initial capital taxes at period 0 are given. This result relies on the separability between consumption and leisure, homotheticity, and the ability of the government to tax di¤erently all generations.

6. Steady State Analysis

The purpose of this section is analyze if there are other type of utility functions that might deliver the zero capital result as an asymptotic property but not along the transition path. In order to study the optimal ...scal policy in the steady state is necessary to have additional assumptions in the government objective function. Let's assume that the government assigns the same weight discounted by time to each generation utility function, formally of its the weight that the government assigns to the generation born at time t; where 2 (0; 1):

$$X_{1\atop t=i}(I_{i}1)$$
 ot i

where $^{\circ}$ parameter indicates how much weight the government values future versus current generations, and $_{i}$ is a positive constant. Using this objective functions, the ...rst-order conditions for steady state are,

(39)
$$\frac{1}{\circ} = 1_{i} \pm F_{K}$$

$$(40) \quad \frac{V_{\cdot i}}{V_{ci}} = i F_{\perp} (2^{i}); \qquad 8$$

(41)
$$V_{ci} = \frac{1}{2} V_{ci+1};$$
 8i

A feature of this model, is that if the economy converges to the steady state, this is independent of the initial conditions and the transition path, see Escolano (1992). The government discount factor determines the interest rate in steady state. For the general type of utility functions that are additively separable capital taxes are zero in steady state, because the new type of constraint optima allocations is a subset of the general welfare function. With non-separable utility functions Chamley (1986) result can be proved under

additional assumptions on the government discount factor and the endowment of eciency units.

Proposition 5. If the utility function is of this type:

(42)
$$u(c; \hat{ }) = \frac{c^{1_i} \frac{34}{4}}{1_i \frac{34}{4}} ch(\hat{ })$$

and $\bar{}$ = $^{\circ}$, and 21 = ::: = 21 ; then capital taxes will be zero in steady state

Proof. The basic underling in this proof is that under this assumptions, from the planner point of view, this economy is equivalent to an in...nite lived agents economy. If the planner and households discount factors are the same, then the redistributive condition implies that all agents will have the same marginal rates of substitution. That, does not mean that all agents will achieve the same allocation in terms of consumption and leisure because agents are endowed with di¤erent e¢ciency units of labor. The additional assumption of equal e¢ciency units across generations ensures that all households will achieve the same allocation in terms of consumption and leisure at each period. Hence this condition will imply that marginal rates of substitution between consumption and leisure will be equal across generations. Therefore this model perfectly behaves as a representative consumer economy, and reproduces Chamley (1986) result.

Formally this is straightforward by comparing the ...rst-order conditions of the competitive equilibrium in steady state,

(43)
$$1 = (1 + r(1_i \mu_i))$$

with the Ramsey excient allocation (under this assumptions $U_{c^i}\,=\,U_{c^{i\,+\,1}})$:

$$1 = (1_i \pm F_k)$$

then it must be the case that $\mu_i = 0$; for all i:

7. Incomplete Set of Instruments

An important assumption in the previous section is that the government can perfectly discriminate taxes among di¤erent generations. Suppose the tax system does not allow tax rates in capital returns or labor income di¤er across consumers. Escolano (1992) analyses a similar model imposing this additional assumption, but uses the dual approach of optimal ...scal policy. Adding this assumption imposes additional restriction on the Ramsey problem because restricts the set of instruments that the government can use to implement the e¢cient allocation. Let's consider ...rst the restriction that taxes in capital returns must be equal across households, that is $\mu_i = \mu$ for all i. The additional restrictions that must be added in the Ramsey problem can be derived from the intertemporal ...rst-order conditions in the competitive equilibrium,

(44)
$$\frac{U_{c_t^i}}{U_{c_t^{i+1}}} = (1 + r_{t+1}(1_i \mu_{t+1}));$$
 8t; i

which implies that the right hand side is equal for all i; therefore any competitive equilibrium must satisfy

(45)
$$\frac{U_{c_{t+1}^{i}}}{U_{c_{t+1}^{i+1}}} = ::: = \frac{U_{c_{t+1}^{i-1}}}{U_{c_{t+1}^{i}}}; \qquad 8t; \quad i = 1; :::; I$$

As in the previous case, this additional restrictions can be added in the government objective function, introducing the associate Lagrange multiplier as a co-state variable. Let A_t^i be the Lagrange multiplier of this additional sequence of I_i 1 constraints for each period.

Now let's assume that taxes on labor income must be equal across consumers, $\zeta_{i;t} = \zeta$ 8i; t. Then, the additional restriction on allocations imply that any competitive equilibrium must satisfy:

$$\frac{\mathsf{U}_{\mathsf{c}^1}}{\mathsf{U}_{\mathsf{c}^1}}\, \mathsf{c}^{\, \mathsf{2}^1} = \ldots = \frac{\mathsf{U}_{\mathsf{c}^1}}{\mathsf{U}_{\mathsf{c}^1}}\, \mathsf{c}^{\, \mathsf{2}^1}$$

The main conclusions is that with this additional assumption capital taxes are not generally zero in steady state, only for some speci...c government discount factor he obtains the standard result.

8. Conclusions

This paper introduces the theory of optimal taxation in economies were agents have a ...nite lifetime. This approach departs from the pioneer works of Auerbach and Kotliko¤ (1987) and introduces the government in the economy as an active agent that chooses the optimal ...scal policy. The theory of optimal taxation is applied to answer how to determine the optimal ...scal policy in the transition path converging to the steady state. It can be shown that if the government has a complete set of taxes (age speci...c taxes) and the utility function is additively separable, then capital taxes are zero in the transition path after the second period. More over, with additional assumptions on the discount factor and the endowment of e⊄ciency units, it can be proved that with non-separable utility functions is not optimal tax capital in steady state.
