paul.lambert@le.ac.uk

Nordic and Baltic Stata Users Group Meeting, Stockholm 7th September 2007

## Fractional Polynomials

- Fractional Polynomials are used in regression models to fit non-linear functions.
- Often preferable to cut-points.
- Functions from fractional polynomials more flexible than from 'standard' polynomials.
- See (Royston and Altman, 1994) or (Sauerbrei and Royston, 1999) for more details.
- Implemented in Stata with fracpoly and mfp commands.

## Powers

- The linear predictor for a fractional polynomial of order $M$ for covariate $x$ can be defined as,

$$
\beta_{0}+\sum_{m=1}^{M} \beta_{m} x^{p_{m}}
$$

- where each power $p_{m}$ is chosen from a restricted set.
- The usual set of powers is

$$
\{-2,-1,-0.5,0,0.5,1,2,3\}
$$

- $x^{0}$ is taken as $\ln (x)$

## Selecting the Best Fitting Model

- All combinations of powers are fitted and the 'best' fitting model obtained.
- Using the default set of powers for an FP2 model there are
- 8 FP1 Models
- 36 FP2 Models (including 8 repeated powers)
- The best fitting model for fractional polynomials of the same degree can be obtain by minimising the deviance.
- When comparing models of a different degree, e.g. FP2 and FP1 models, the model can be selected using a formal significance test or the Akaike Information Criterion (AIC).

## Selecting the Best Fitting Model

- All combinations of powers are fitted and the 'best' fitting model obtained.
- Using the default set of powers for an FP2 model there are
- 8 FP1 Models
- 36 FP2 Models (including 8 repeated powers)
- The best fitting model for fractional polynomials of the same degree can be obtain by minimising the deviance.
- When comparing models of a different degree, e.g. FP2 and FP1 models, the model can be selected using a formal significance test or the Akaike Information Criterion (AIC).
- Model selection uncertainty is ignored.

## German Breast Cancer Study Group Data

- 686 women with primary node positive breast cancer (Sauerbrei and Royston, 1999).
- Time to recurrence or death (299 events).
- Covariates include,
- Age (years)
- Menopausal staus
- Tumour Size (mm)
- Tumour Grade
- Number of positive lymph nodes
- Progesterone Receptor (fmol)
- Oestrogen Receptor (fmol)
- Hormonal Therapy

## German Breast Cancer Study Group Data

- 686 women with primary node positive breast cancer (Sauerbrei and Royston, 1999).
- Time to recurrence or death (299 events).
- Covariates include,
- Age (years)
- Menopausal staus
- Tumour Size (mm)
- Tumour Grade
- Number of positive lymph nodes
- Progesterone Receptor (fmol)
- Oestrogen Receptor (fmol)
- Hormonal Therapy
- 5 covariates were selected using mfp command.

## Breast Cancer - Best Fitting Model for Age

Best Fitting Model (-2 -.5), AIC $=3562.73$

## Breast Cancer - Best Fitting Model for Age

Best Fitting Model (-2 -.5), AIC $=3562.73$

FP2(-2 -0.5): $\ln (h(t))=\ln \left(h_{0}(t)\right)+\beta_{1}$ Age $_{*}^{-2}+\beta_{2}$ Age $_{*}^{-0.5}$

## Breast Cancer - The 5 Best Fitting Model for Age

| Powers | AIC |
| :---: | :---: |
| $(-2,-0.5)$ | 3562.73 |
| $(-1,-1)$ | 3562.77 |
| $(-2,-1)$ | 3562.78 |
| $(-2,0)$ | 3562.83 |
| $(-2,0.5)$ | 3563.05 |

## Breast Cancer - Age

Best Fitting Model (-2 -.5), AIC $=3562.73$

## Breast Cancer - Age

Powers (-1 -1), AIC = 3562.77

## Breast Cancer - Age

Powers (-2 -1), AIC = 3562.78

## Breast Cancer - Age

Powers (-2 0), AIC = 3562.83

## Breast Cancer - Age

## Breast Cancer - No. Positive Lymph Nodes

Best Fitting Model (1 2), AIC $=3498.99$

## Breast Cancer - No. Positive Lymph Nodes

Powers (-1 -1), AIC = 3499.05

## Breast Cancer - No. Positive Lymph Nodes

Powers (-2 -.5), AIC = 3499.12

## Breast Cancer - No. Positive Lymph Nodes

Powers (-2 -1), AIC = 3499.44

## Breast Cancer - No. Positive Lymph Nodes

## Model Averaging 1

- In FP models the model selection process is usually ignored when calculating fitted values and their associated confidence intervals.
- Model Averaging is popular Bayesian research area (Hoeting et al., 1999), (Congdon, 2007).
- Increasing interest from frequentist perspective (Burnham and Anderson, 2004) (Buckland et al., 2007) (Congdon, 2007) (Faes et al., 2007)
- Usually interest lies in model averaging for a parameter.
- Here we are interested in averaging over the functional form obtained from different models.

## Model Averaging 2

- If there are $K$ contending models, $M_{k}, k=1, \ldots, K$ with weights, $w_{k}$, which are scaled so that $\sum w_{k}=1$, then the estimate of a parameter or quantity, $\theta$ (assumed to be common to all models) is taken to be,

$$
\widehat{\theta}_{a}=\sum_{k=1}^{K} w_{k} \widehat{\theta}_{k}
$$

- The variance of $\widehat{\theta}_{a}$ is,

$$
\operatorname{var}\left(\widehat{\theta}_{a}\right)=\sum_{k=1}^{K} w_{k}^{2}\left(\operatorname{var}\left(\widehat{\theta}_{k} \mid M_{k}\right)+\left(\hat{\theta}_{k}-\widehat{\theta}_{a}\right)^{2}\right)
$$

## Obtaining the Weights, $w_{k}$

- In a Bayesian context we want, $w_{k}=P\left(M_{k} \mid\right.$ Data $)$
- These probabilities are not trivial to calculate and various approximations are available.
- One such approximation is to use the Bayesian Information Criterion (BIC)

$$
B I C_{k}=\ln \left(L_{k}\right)-\frac{1}{2} p \ln (n)
$$

- The AIC can also be used to derive the model weights (Buckland et al., 2007)

$$
A I C_{k}=\ln \left(L_{k}\right)-2 p
$$

- Recently Faes used the AIC to derive model weights for fractional polynomial models (Faes et al., 2007).

## Obtaining the Weights, $w_{k}$

- Let

$$
\Delta_{k}=B I C_{k}-B I C_{\min } \quad \text { or } \quad \Delta_{k}=A I C_{k}-A I C_{\min }
$$

- The weights, $w_{k}$, are then defined as,

$$
w_{k}=\frac{\exp \left(\frac{1}{2} \Delta_{k}\right)}{\sum_{j=1}^{K} \exp \left(\frac{1}{2} \Delta_{j}\right)}
$$

## Using Bootstrapping to Obtain the Weights, $w_{k}$

- An alternative to using the AIC or BIC for the model weights, $w_{k}$, is to use bootstrapping (Holländer et al., 2006).
- For each bootstrap sample the best fitting fractional polynomial model is selected.
- The weights $w_{k}$, are simply obtained using the frequencies of the models selected over the $B$ bootstrap samples.
- If comparing fractional polynomial models of different degrees then some selection process is needed. This is usually done by setting a value for $\alpha$.

## Using fpma

## Using fpma

| fpma x1, ic(aic) xpredict: stcox x1 Models Included (in order of weight) |  |  |  |  |  |  |

## Multivariable Fractional Polynomials

- The above only really applies when using fractional polynomials for only one of the covariates in the model.
- However, is is common to use models with fractional polynomials for more than one covariate.
- A simple approach is to model average over various fractional polynomial models for the covariate of interest, while keeping the functional form of the remaining covariates constant.
- The usemfp option will do this for you.

## Model Averaging after mfp - No. of Positive Lymph Nodes

AIC weights

## Discussion

- Fractional Polynomials very useful for modelling non-linear functions.
- Model selection uncertainty is usually ignored after final model is obtained.
- Model averaging is easy to implement and incorporates FP model selection uncertainty.
- Still further work needed. For example,
- Statistical properties (coverage etc).
- Comparison with fully Bayesian model averaging.
