Opencagegeo: Stata Module for Geocoding

Lars Zeigermann
Düsseldorf Institute for Competition Economics (DICE) & Monopolies Commission
Germany
lars.zeigermann@monopolkommission.bund.de

Abstract. This article describes opencagegeo and its (simplified) immediate version opencagegeoi, which allow the user to obtain latitudes and longitudes for addresses (forward geocoding) and retrieve addresses from latitude longitude pairs (reverse geocoding). opencagegeo uses OpenCage Data’s geocoding application programming interface (API) which has very flexible terms of use. Contrary to other geocoders in Stata (using Google Maps’, MapQuest’s or HERE Maps’ APIs), OpenCage Data does not restrict the use of geocodes and explicitly allows data storage.

Keywords: opencagegeo, geocoding, reverse geocoding, OpenCage Data

1 Introduction
Spatial information is extensively used by researchers and practitioners in numerous fields and (forward and reverse) geocoding has become a common exercise. Forward geocoding is the process of converting an address into geographic coordinates. Reverse geocoding uses geographic coordinates to retrieve the postal address.

To facilitate geocoding for Stata users, a number of user-written geocoding routines have been made available. They use so-called APIs (application programming interfaces) to access online geocoding services. These are (the outdated) geocode (Ozimek and Miles 2011), its (no longer available) successor geocode3 (Bernhard 2013) and the immediate command gcode (Ansari 2015) using Google Maps’ API, geocodeopen (Anderson 2013) using MapQuest’s API and geocodehere (Hess 2015) using Here Maps’ API. However, the terms of use of Google Maps, MapQuest and Here Maps are very restrictive and prohibit storing data, which makes them inappropriate for most purposes.

Here, opencagegeo’s major advantage comes into play: the flexible terms of use of OpenCage Data’s geocoding API it is using. All data is jointly licensed under the ODbL and CC-BY-SA licenses1 and OpenCage Data does not restrict the use of geocodes.2

The syntax of opencagegeo and its immediate version opencagegeoi is described in Section 2 and Section 3. Two short examples are provided in Section 4.

1The ODbL and CC-BY-SA licences are available at http://opendatacommons.org/licenses/odbl/summary/ and https://creativecommons.org/licenses/by-sa/2.0/.
2OpenCage Data’s terms of use are available at http://geocoder.opencagedata.com/faq.html#legal.
2 Opencagegeo

2.1 Syntax

```python
opencagegeo [if] [in] [ , key(string) number(varname) street(varname)
               postcode(varname) city(varname) county(varname) state(varname)
               country(varname) fulladdress(varname) latitude(varname) longitude(varname)
               coordinates(varname) fulladdress(varname) language(varname or string)
               replace resume ]
```

2.2 Options

General

**key (string)** is required and specifies the OpenCage Data API key.

**countrycode (varname or string)** specifies the country code. `countrycode()` allows either a string variable or a string as input.

**language (varname or string)** specifies the language in which the results are returned. `language()` allows either a string variable or a string as input. The default is `en` for English.

**resume** specifies that the process is continued after the rate limit was exceeded the day before. **resume** may not be combined with **replace**.

Forward Geocoding

**number (varname)** specifies the variable containing the house number.

**street (varname)** specifies the variable containing the street. **varname** must be string.

**postcode (varname)** specifies the variable containing the postal code.

**city (varname)** specifies the variable containing the city, town or village. **varname** must be string.

**county (varname)** specifies the variable containing the county. **varname** must be string.

**state (varname)** specifies the variable containing the state. **varname** must be string.

**country (varname)** specifies the variable containing the country. **varname** must be string.

**fulladdress (varname)** specifies a single variable containing some or all of the above options.
varname must be string. fulladdress() may not be combined with any of the above options.

Reverse Geocoding

\texttt{latitude(varname)} specifies the variable containing the latitude. Values must lie between -90 and 90.

\texttt{longitude(varname)} specifies the variable containing the longitude. Values must lie between -180 and 180.

\texttt{coordinates(varname)} specifies the variable containing latitude longitude pairs. Latitudes must lie between -90 and 90 and must be stated first. Longitudes must lie between -180 and 180. Both values must be separated by a comma. varname must be string. coordinates() may not be combined with \texttt{latitude()} and \texttt{longitude()}.

2.3 Remarks

General

\texttt{opencagegeo} requires an OpenCage Data API key which can be obtained by signing up at https://geocoder.opencagedata.com/users/sign_up. The user can choose among a number of customer plans with different daily rate limits. The free trial allows 2,500 requests per day. If the rate limit is hit, \texttt{opencagegeo} will issue an error message and exit. To continue the task on the following day, the user may simply add the \texttt{resume} option to the original specification. \texttt{opencagegeo} will automatically detect which observations are still to be geocoded. The user is strongly advised not to make any changes to the data until geocoding of all observations is completed.\footnote{The \texttt{resume} option evaluates the output variable \texttt{g.quality} to select observations which have not yet been geocoded.} A new day begins at 00:00:00 Coordinated Universal Time (UTC).

If the variables \texttt{opencagegeo} creates, see Section 2.4 below, already exist, the user can specify \texttt{replace} to overwrite existing observations. If either \texttt{in} or \texttt{if} is specified, only the selected observations will be replaced. \texttt{resume} and \texttt{replace} may not be combined.

The \texttt{countrycode()} option allows the user to specify the country of the location. Providing a country code will restrict the results to the given country. If all locations lie in the same country, the user may enter the country code directly into \texttt{countrycode()}. Alternatively, if the locations are in more than just one country, a variable containing the respective country codes needs to be specified. The country code is a two letter code as defined by the ISO 3166-1 Alpha 2 standard.\footnote{A comprehensive list of all ISO 3166-1 Alpha 2 codes is available at https://www.iso.org/obp/ui/#search.} If any country code is invalid, \texttt{opencagegeo} will issue an error message and exit.

The \texttt{language()} option allows the user to specify the language in which the results are re-
turned. As with `countrycode()`, either a string or a string variable can be specified. The language must be entered in IETF format language code. The default is English. If the language is set to `native`, the results will be returned in the native language of the location - provided the underlying OpenStreetMap (OSM) data is available in that language. Users of Stata 13 or older are advised to use the `language()` option carefully as many languages other than English contain special characters which cannot be displayed properly.

`opencagegeo` requires two user-written Stata libraries, `insheetjson` and `libjson` (Lindsley 2012a,b), which are available at Statistical Software Components.

**Forward geocoding**

Generally, there are two different ways of feeding addresses into `opencagegeo`. Firstly, by components using the `street()`, `number()`, `postcode()`, `city()`, `county()`, `state()` and `country()` options. This is recommended if the location address data is provided in separate variables. Not all options need to be specified at the same time; they can be combined in any meaningful way. To obtain geocodes of, let’s say, cities, you may use `city()`, `state()` and `country()`.

Secondly, if the address is contained in a single string variable, the `fulladdress()` option may be employed. The address should follow the country specific conventions, although the OpenCage Geocoder allows for some flexibility. A well-formatted address could look like:

"number street, city postal code, county, state, country"
"street number, postal code city, county, state, country"

Generally, the OpenCage Geocoder is not case sensitive and can deal with commonly used abbreviations. Running `opencagegeo` in Stata 14 (or newer) allows the address variables to be in Unicode (UTF-8). That is address names may contain accented characters, symbols and non-latin characters. For older releases, the input variables must not contain any special characters. Otherwise, `opencagegeo` will issue an error message and exit. `opencagegeo` is sensitive to spelling mistakes and will return empty strings for misspelled location addresses.

**Reverse geocoding**

As with forward geocoding, two options are available for reverse geocoding. If longitudes and latitudes are contained in two separate variables, the `latitude()` and `longitude()` options should be used.

Alternatively, latitude longitude pairs may be fed into the `coordinates()` option. Latitudes need to be stated first and both values must be separated by a comma.

---

6 Only ASCII printable characters, i.e. character codes 32-127, may be used in the input variables.
Otherwise, opencagegeo will issue an error message and exit.

2.4 Output variables

Running opencagegeo generates a set of 12 variables, all having \texttt{g}-prefixes.\footnote{The JSON paths used to extract the results returned from the OpenCage Geocoder are given in the appendix.}

\texttt{g\_latitude} and \texttt{g\_longitude} contain the latitudes and longitudes retrieved. The variables \texttt{g\_number}, \texttt{g\_street}, \texttt{g\_postcode}, \texttt{g\_city}, \texttt{g\_county}, \texttt{g\_state} and \texttt{g\_country} contain the respective information returned. If the information is missing (e.g. the house number is not known) or not requested (\texttt{number()} was not specified or no information on the house number was contained in address variable fed into the \texttt{fulladdress()} option), an empty string for the respective variable will be returned. \texttt{g\_formatted} contains a well-formatted place name generated by the OpenCage Geocoder. In addition to the postal address, it might also have additional information on the name of the building, institution, shop etc. at that location.

Finally, \texttt{g\_confidence} and \texttt{g\_quality} are generated. The former provides a measure of precision of the match and is directly returned from the OpenCage Geocoder. The confidence value is calculated as the distance in kilometres between the South-East and the North-West corners of the bounding box. Confidence levels are defined as follows:

\begin{itemize}
  \item 0 = unable to determine bounding box
  \item 1 = 25 km or more
  \item 2 = less than 25 km
  \item 3 = less than 20 km
  \item 4 = less than 15 km
  \item 5 = less than 10 km
  \item 6 = less than 7.5 km
  \item 7 = less than 5 km
  \item 8 = less than 1 km
  \item 9 = less than 0.5 km
  \item 10 = less than 0.25 km
\end{itemize}
The variable `g.quality` contains the accuracy level of the returned results and is defined as follows:

- 0 = location not found
- 1 = country
- 2 = state
- 3 = county
- 4 = city
- 5 = postcode
- 6 = street
- 7 = number

If, for example, the returned results for an address contains information down to the postal code level, but the street and the house number were not found, the quality level will be `postcode`. The highest quality level to be reached is hence determined by the inputs; if the `number()` is not specified or no information on the house number is contained in the variable fed into `fulladdress()`, the highest quality level to be achieved is `street`.

3 Opencagegeoi

3.1 Syntax

`opencagegeoi #location`

3.2 Remarks

The immediate `opencagegeoi` takes its inputs from what is typed as arguments rather than from data stored in the memory. Instead of creating output variables it immediately displays the results in the output window.

`opencagegeoi` requires the API key to be stored in a global macro `mykey`. The location to be geocoded is then directly entered after `opencagegeoi`. For forward geocoding, the input should be well-formatted as described above. For reverse geocoding, `opencagegeoi` accepts a latitude longitude pair. The latitude is entered first and both values must be separated by a comma.

The user may also define a global macro `language` containing the IETF code of the language in which the result shall be returned. The default is English. If the user sets the language to `native`, the results are returned in the native language of the location. Users of Stata 13 or older should be aware that special characters cannot be displayed properly.

3.3 Saved results

In addition to displaying the well-formatted address returned from the OpenCage Geocoder and the latitude and longitude values, `opencagegeoi` saves the following results to `r()`.
4 Examples

4.1 Opencagegeo

Forward Geocoding

As an example consider the addresses of five Goethe Institutes in Europe, Mexico and the United States.\(^8\) The data is displayed below.

```
. list
```

<table>
<thead>
<tr>
<th>CITY</th>
<th>POSTCODE</th>
<th>STREET</th>
<th>NUMBER</th>
<th>COUNTRY</th>
</tr>
</thead>
<tbody>
<tr>
<td>London</td>
<td>SW7 2PH</td>
<td>Exhibition Road</td>
<td>50</td>
<td>UK</td>
</tr>
<tr>
<td>Mexico City</td>
<td>06700</td>
<td>Tonala</td>
<td>43</td>
<td>Mexico</td>
</tr>
<tr>
<td>New York</td>
<td>10003</td>
<td>Irving Place</td>
<td>30</td>
<td>USA</td>
</tr>
<tr>
<td>Paris</td>
<td>75116</td>
<td>Avenue d’Iena</td>
<td>17</td>
<td>France</td>
</tr>
<tr>
<td>Rome</td>
<td>00198</td>
<td>Via Savoia</td>
<td>15</td>
<td>Italy</td>
</tr>
</tbody>
</table>
```

To geocode the five locations given above, we specify `opencagegeo` as follows:

```
. opencagegeo, key(YOUR-KEY-HERE) street(STREET) number(NUMBER) postcode(POSTCODE) > country(COUNTRY)
```

```
OpenCage geocoded 1 of 5
(output omitted)
OpenCage geocoded 5 of 5
```

```
<table>
<thead>
<tr>
<th>g_quality</th>
<th>Freq.</th>
<th>Percent</th>
<th>Cum.</th>
</tr>
</thead>
<tbody>
<tr>
<td>street</td>
<td>1</td>
<td>20.00</td>
<td>20.00</td>
</tr>
<tr>
<td>number</td>
<td>4</td>
<td>80.00</td>
<td>100.00</td>
</tr>
</tbody>
</table>
```

Data generated is jointly licensed under the ODbL and CC-BY-SA licenses.

The output table produced by `opencagegeo` illustrates that four out of five addresses were identified at the highest quality level, i.e. `number`. For one location, the exact house number was not found and the resulting quality level is `street`.

Reverse Geocoding

Now, we want to reverse geocode the latitudes and longitudes generated above. First, we rename the variables and then specify `opencagegeo` using `latitude()`, `longitude()` and the `replace` option.

\(^8\)The Goethe Institute is a non-profit German cultural association promoting the German language, the addresses are obtained from https://www.goethe.de/en/wwt.html.
Not surprisingly, we find that four latitude longitude pairs are identified at the number and one at the street level.

4.2 Opencagegeoi

Forward Geocoding

If we intend to geocode a single location only and want the results to be displayed in the output window rather than saved as variables, we should use the immediate version opencagegeoi. Note, however, that we need to define a global macro mykey first.9

```
. global mykey YOUR-KEY-HERE
```

To obtain the geographic coordinates of the Goethe Institute London, we specify opencagegeoi as following:

```
. opencagegeoi 50 Exhibition Road, London SW7 2PH, UK
```

```
*********************************
*** OpenCage Geocoder Results ***
*********************************
Formatted address: Goethe Institute, 50-51 Exhibition Road, London SW7 1BF, UK
Latitude: 51.4994811
Longitude: -0.174013268370617
```

Reverse Geocoding

To retrieve the postal address from geographic coordinates - in our example of the Goethe Institute in London - we type:

```
. opencagegeoi 51.4994811,-0.174013268370617
```

9The global macro mykey needs to be specified only once when a new Stata window is opened.
5 Appendix

The OpenCage Geocoder API returns its results in JSON (JavaScript Object Notation) format. The respective information is then extracted and stored in the variables described above (or displayed immediately in the case of open cage geo). As the underlying data (provided by OpenStreetMap (OSM) and other open data sources) is maintained by many contributors, keys are not uniquely defined. The key leading to, let’s say, the street name is not always street, but may be street name, road etc. instead. Unfortunately, there exists no exhaustive list of all these aliases, however, open cage geo uses the most common ones to generate its output variables. The so-called JSON paths which are used for extracting the data are reported in the table below.

<table>
<thead>
<tr>
<th>Variable</th>
<th>JSON path (aliases)</th>
</tr>
</thead>
<tbody>
<tr>
<td>g_latitude</td>
<td>results:1:geometry:lat</td>
</tr>
<tr>
<td>g_longitude</td>
<td>results:1:geometry:lng</td>
</tr>
<tr>
<td>g_street</td>
<td>results:1:components:street (street_name, road, residential, footway, pedestrian)</td>
</tr>
<tr>
<td>g_number</td>
<td>results:1:components:house_number</td>
</tr>
<tr>
<td>g_postcode</td>
<td>results:1:components:postcode</td>
</tr>
<tr>
<td>g_city</td>
<td>results:1:components:city (town, village, hamlet)</td>
</tr>
<tr>
<td>g_county</td>
<td>results:1:components:county</td>
</tr>
<tr>
<td>g_state</td>
<td>results:1:components:state</td>
</tr>
<tr>
<td>g_country</td>
<td>results:1:components:country</td>
</tr>
<tr>
<td>g_formatted</td>
<td>results:1:components:formatted</td>
</tr>
<tr>
<td>g_confidence</td>
<td>results:1:components:confidence</td>
</tr>
</tbody>
</table>

The JSON paths used by open cage geo are the same as for the respective variables generated by open cage geo.

6 Acknowledgements

I would like to thank Ed Freyfogle of OpenCage Data for his support and Achim Ahrens for testing open cage geo and helping improve it. I also thank the authors of the existing geocoding

---

10 If none of the keys used by open cage geo lead to the requested information, an empty string in the respective variable will be returned. However, the information will be part of the well-formatted address in g_formatted.
routines for Stata, especially Adam Ozimek and Daniel Miles (geocode). Parts of opencagegeo
build upon their code. The immediate version was added at Kit Baum’s suggestion. All remaining
errors are my own. Comments and suggestions are welcome.
